Instructions to Authors

Contributions illustrated by scanning electron micrographs of Ostracoda in stereo-pairs are invited. Format should follow the style set by the majority of papers in this issue. Descriptive matter apart from illustrations should be cut to a minimum; preferably each plate should be accompanied by one page of text only. Blanks to aid in mounting figures for plates may be obtained from any one of the Editors or Editorial Board. Completed papers should be sent to Dr David J. Siveter.

The front cover shows a female left valve of Hemicythere villosa (Sars, 1866)

Holotype: Sektion Geologische Wissenschaften, University of Greifswald, German Democratic Republic; no.

29/15, posteriorly incomplete ♀LV.

Type locality: Beach at Dornbusch, Isle of Hiddensee (Baltic Sea), Germany; lat. 54°36′N, long. 13°7′E,

Backsteinkalk erratic boulder (no. and type 1B1; equivalent of the upper Viruan Skagen Limestone

of Central Sweden), middle Ordovician.

Figured specimens: Geologisch-Paläontologisches Institut und Museum, University of Hamburg (GPIMH) nos. 2739

(\$RV: Pl. 11, 2, fig. 1), 2740 (\$\sigmu\$LV: Pl. 11, 2, fig. 2) and 2741 (posterodorsally incomplete \$\frac{2}{LV}\$: Pl. 11, 4, figs. 1, 2). Nos. 2739 and 2740 are from Backsteinkalk erratic boulder no. Gis 30 (type 1B14; equivalent of the upper Viruan upper Dalby Limestone of Central Sweden), from the beach of Gislövshammar, \$\frac{2}{L}\$ Scania, \$\frac{2}{L}\$ Sweden; lat. \$\frac{2}{L}\$ Soll. by the author in 1978. No. 2741 is from Backsteinkalk erratic boulder no. \$\frac{2}{L}\$ (type 1B1), from the beach at \$\frac{2}{L}\$ Staberhuk, Isle of \$\frac{2}{L}\$ Fehmarn (Baltic \$\frac{2}{L}\$), \$\frac{2}{L}\$ Germany; lat. \$\frac{2}{L}\$ Soll. by the author in 1980.

Explanation of Plate 11, 2

Fig. 1, $\Re N$, ext. lat. (GPIMH 2739, 1.13 mm long excluding spines); fig. 2, $\Im N$, ext. lat. (GPIMH 2740, 1.05 mm long excluding spines). Scale A (100 μ m; × 72), fig. 1; scale B (100 μ m; × 91), fig. 2.

Stereo-Atlas of Ostracod Shell 11, 3

Hippula turris (3 of 4)

Diagnosis:

Species of *Hippula (Cetona)* with S2 distinct, long and sigmoidal, dorsally rather deep. Preadductorial node rather distinct; a relatively broad, conical bulb. Posteroventral lobe strongly developed, stituated ventrocentrally, ending in a long reticulate spine. Velar flange in males forming an angle with the lateral surface of about 90°, in females rather obtuse. Torus very broad (transverse), nearly (\mathfrak{P}) or as broad (\mathfrak{G}) as velar flange. Adult valves \mathfrak{C} . 1.00–1.13 mmm long (excluding spines). Length: height ratio 1.60–1.80.

Remarks:

Ivanova ($Trud\bar{y}$ -paleont. Inst., 172, 36, 1979) considered the cavities of the "histial" flange of the females of Oecematobolbina as a prototype of the locular type of dimorphism. This is considered impossible because loculi are always formed on the inner side of the dolon (the antrum), not the outer side

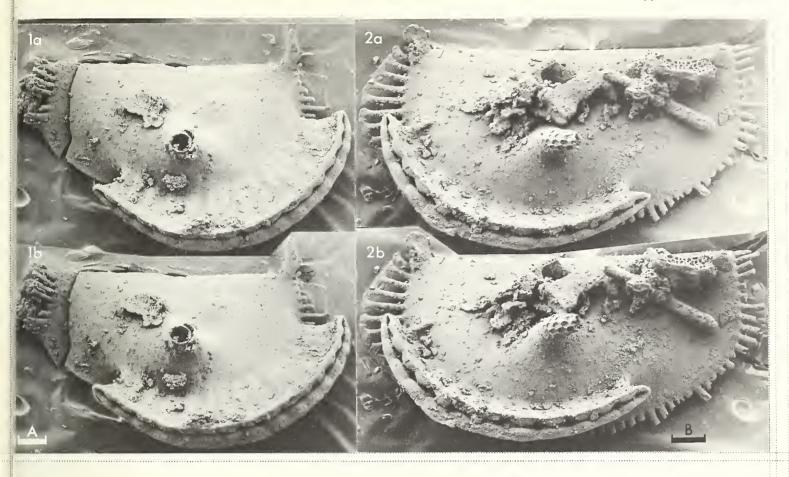

Copeland (Bull. geol. Surv. Can., 347, 16, 1982) considered Schallreuter's subgeneric distinction within Hippula untenable in the light of his material from the District of Mackenzie, Canada. In H. varicata he described the "histium" as consisting of three fluted flanges on the heteromorphic valve, and a single flange on the tecnomorphic valve. He could not observe this phenomenon in the European material. As shown herein (Pl. 11. 2, fig. 2) the males also possess the characteristic torus with an entervening row of diamond-shaped spaces. Perhaps the North American forms exhibit a tendency to reduce the tori. Parahippula ventrospinosa (Kraft, Mem. geol. Soc. Am., 85, 1962) resembles Hippula in having radiating furrows of the velar flange in both dimorphs (op. cit., pl. 11, figs. 14a, 15, 17, pl. 12, figs. 4, 5, 7 cf. Pl. 11, 2, figs. 1, 2). Such furrows could be the rudiments of the cavities. The missing tori in the tecnomorphs of H. varicata could be explained as an example of proterogenesis.

Distribution:

Known only from upper Viruan Backsteinkalk erratic boulders of northern Germany and southern Sweden (types 1B1, 1B3, 1B14, cf. R. E. L. Schallreuter, op. cit., 1970), middle Ordovician.

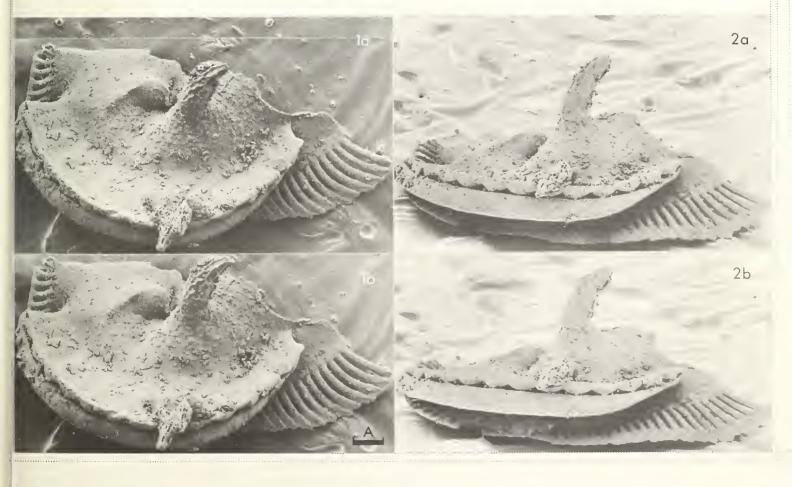

Explanation of Plate 11, 4

Figs. 1–2, posterodorsally incomplete QLV (**GPIMH 2741**, 1.07 mm long excluding spines): fig. 1, ext. lat.; fig. 2, ext. ventrolat. Scale A ($100 \,\mu\text{m}$; \times 82), figs. 1, 2.

ON SCHALLREUTERIA (LIPPEA) LIPPENSIS SCHALLREUTER subgen. et sp. nov.

by Roger E. L. Schallreuter (University of Hamburg, German Federa! Republic)

Genus SCHALLREUTERIA Siveter, 1982

Schallreuteria gen. nov.; D. J. Siveter, Stereo-Atlas of Ostracod Shells, 9, 93–100, pls. 9, 94; 9, 96; 9, 98; 9, 100. Subgenus LIPPEA subgen. nov.

Type-species: Schallreuteria (Lippea) lippensis sp. nov.

Derivation of name:

As for the type-species.

Diagnosis:

Subgenus of Schallreuteria with only one sulcus (S2) and less pronounced quadrilobation.

Remarks:

The type-species of *Schallreuteria*, *S. superciliata* (Reed, 1910), from the Longvillian (Caradoc Series) of England, is distinctly quadrilobate (cf. Siveter, op. cit.) and is thus considered a more conservative form. It belongs to the main line of the genus from which *S. (Lippea)* is separated by its loss of quadrilobation which occured at the latest by the lower upper Viruan (= Harnagian/Soudleyan). The characteristic dorsal spines of lobes L1 and L3 of *S. superciliata* are also present in *S. lippensis* (cf. Siveter, op. cit., Pl. 9, 96, fig. 2).

The main differences between S. (Schallreuteria) and S. (Lippea) are the same as in the genera Rakverella and Pectidolon. Therefore, Pectidolon is now considered to be a subgenus of Rakverella. Rakverella is characterized by special cristae which are not present in Schallreuteria (Siveter, 95).

Schallreuteria (Lippea) lippensis sp. nov.

1970 Rakverella pectinata; R. E. L. Schallreuter, Hercynia N. F., 6, (3), 289, tab. 2 (292, 293) (pars).

1973 Rakverella pectinata (Oepik); W. Neben & H. H. Krueger, Staringia, 2, pl. 92, fig. 5.

Explanation of Plate 11, 6

Figs. 1–4, QLV (holotype, **GPIMH 2900**, 1353 μm long): fig. 1, ext. lat.; fig. 2, ext. vent. obl.; fig. 3, ornament of lateral surface (pillars, removed pillars, and reticulation); fig. 4, detail of surface reticulation.

Scale A (250 μ m; × 58), figs. 1–2; scale B (50 μ m; × 290), fig. 3; scale C (50 μ m; × 225), fig. 4.

Stereo-Atlas of Ostracod Shells 11, 7

Schallreuteria lippensis (3 of 4)

1976 Rakverella pectinata (Öpik); R. E. L. Schallreuter, Palaeontographica (A), **153** (4/6), 203-205 (pars), pl. 6(39), figs. 1, 2. 1983 Rakverella pectinata (Öpik); R. E. L. Schallreuter, Palaeontographica (A), **180** (4/6), 165, 166, 179 (pars), pl. 11, fig. 3.

Holotype: Geologisch-Paläontologisches Institut und Museum, University of Hamburg (GPIMH), no. 2900, ?

LV. [Paratypes: nos. 2902–2904].

Type locality: Lower upper Viruan (middle Ordovician) 14B2-type Backsteinkalk erratic boulder of the Baltic group (cf. R. E. L. Schallreuter 1970, op. cit., 287), no. Lip1, from the beach at Lippe, Hohwacht

Bay, Baltic Sea, Germany; lat. 54° 20.5′ N, long. 10° 38.5′ E.

Derivation of name:

After the type locality.

Figured specimens:

GPIMH nos. **2900** (\$LV: Pl. 11, 6, figs. 1–4; Pl. 11, 8, fig. 2), **2902** (\$RV: Pl. 11, 8, fig. 1) and **2901** (\$RV: Pl. 11, 8, fig. 3). Nos. **2900** and **2902** are from the type locality; boulder collected by the author in July 1983. No. **2901** is from Backsteinkalk erratic boulder no. G29 (cf. Schallreuter 1983,

op. cit., 165); lat. 57° 18' N, long. 18° 8' E.

Diagnosis:

Species of S. (Lippea) with L1 as a strong, broad dorsal spine, L2 a slender dorsal spine; weak preadductorial node and weak anteroventral node; L3 an elongate lobe with strong dorsal spine and weak posteroventral lobe-like elevation; L4 a slender dorsal spine and very weak ventral inflation. Only weak laterovelar furrow. Special reticulation (net standing on pillars), different on lateral

surface and dolon. Females 1.30–1.39 mm long.

Remarks:

The material was formerly assigned by Schallreuter (1983) to Rakverella pectinata (Öpik), which was considered by Henningsmoen (1953) and Sarv (1959) as synonymous with R. bonnemai (Schallreuter 1976, op. cit., 204). The more abundant and better preserved material now in hand shows that the material does not belong to R. pectinata and that Henningsmoen and Sarv were apparently correct in considering that species synonymous with R. bonnemai. The holotype of R. pectinata is a steinkern, but the size and arrangement of the posterior spines is similar to that of

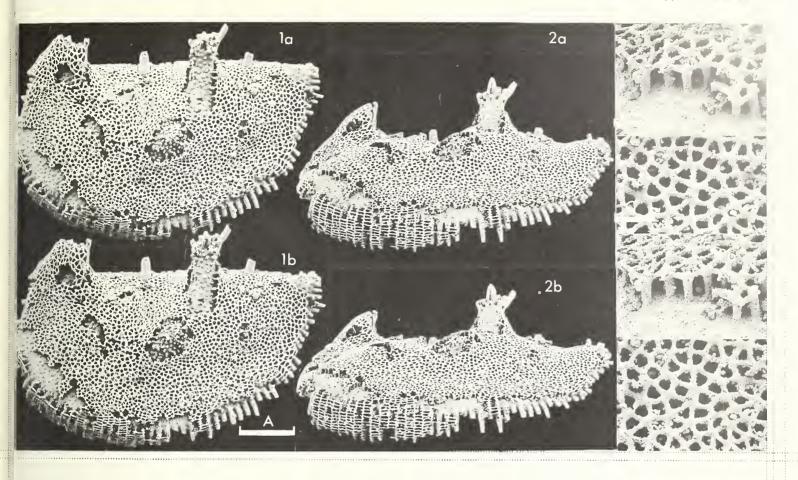

R. bonnemai.

Distribution:

Backsteinkalk erratic boulders (14B2-type) of northern Germany and Sweden (Isle of Gotland, Baltic Sea). Boulders Lip1, 14B2, 812, G14, G29 and G39; middle Ordovician.

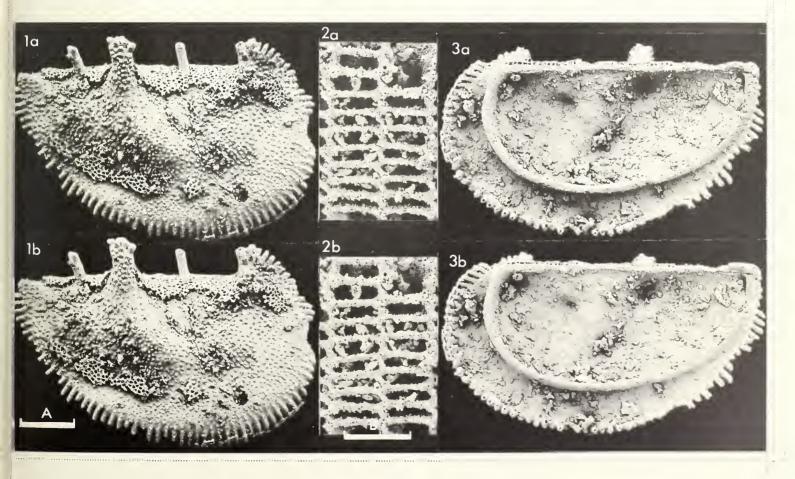

Explanation of Plate 11, 8

Fig. 1, $\Re N$, ext. lat. (paratype, **GPIMH 2902**, 1314 μ m long); fig. 2, $\Re N$, detail of ornament of dolon (holotype, **GPIMH 2900**); fig. 3, $\Re N$, int. lat. (**GPIMH 2901**, 1390 μ m long). Scale A (250 μ m; × 59.5), figs. 1, 3; scale B (50 μ m; × 350), fig. 2.

Stereo-Atlas of Ostracod Shells 11, 8

Schallreuteria lippensis (4 of 4)

595.336.13 (113.313) (430.2 : 161.011.50) : 551.35 + 552.55

ON DURINGIA SPINOSA (KNÜPFER)

by Roger E. L. Schallreuter (University of Hamburg, German Federal Republic)

Genus DURINGIA gen. nov.

Type-species: Eurychilina spinosa Knüpfer, 1968

Derivation of name:

Duringia, an old name for Thüringen, the country of the type locality of the type-species.

Diagnosis:

A medium-sized, possible genus of the Piretellinae, with \$2 long and sigmoidal and preadductorial node as a distinct bulb. Tecnomorphic velum appears as a row of spines. Females with a strongly convex tubulose dolon, having a row of spines sited at the border of the lateral and marginal surfaces.

Lateral surface spinose.

Remarks:

The presumably tubulose velum places the genus within the Eurychilinacea. The female velum mostly resembles that of *Piretella* (cf. Schallreuter, *Palaeontographica* (A) 149 (4/6), pl. 26(5), figs. 1, 4, 6, pl. 27(6), fig. 1) but the dolonal spines are missing in *Piretella*. Another distinguishing feature is the long sigmoidal S2 of Duringia which is present elsewhere notably in the Oepikiidae (Schallreuter, op. cit., 175). The assignment of *Duringia* to the Piretellinae (Eurychilinidae) is therefore questionable.

With respect to the tecnomorphic velar spines and the female dolonal spines Duringia strongly resembles *Hithis* (cf. Schallreuter, *Palaeontographica* (A), 144 (1/3), pl. 17, figs. 1–3, 1973; Schallreuter & Siveter, Stereo-Atlas Ostracod Shells, 9 (2) 15, 85-88, 1982), Piretia (Schallreuter, op. cit., pl. 17, fig. 7, pl. 18, fig. 1) and Bromidella (Copeland, Bull. geol. Surv. Can., 347, pl. 2, figs. 21, 22, 1982), but in all these cases the dolon exhibits no tubules.

Explanation of Plate 11, 10

Fig. 1, dors. and posterovent. incomplete ? LV, ext. lat. (GPIMH 2727, 1.19 mm long); fig. 2, fragmentary LV, int. obl. (GPIMH 2728); fig. 3, posterovent. incomplete tecnomorphic LV, ext. lat. (GPIMH 2729, 0.83 mm long excluding spines). Scale A (100 μ m; × 65), figs. 1, 2; scale B (100 μ m; × 90), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 11

Duringia spinosa (3 of 4)

Duringia spinosa (Knüpfer, 1968)

1963 Eurychilina; H.Blumenstengel et. al., Geol. Ges. DDR Exkursionsführer zur Herbsttagung, 1963, 6.

1968 Eurychilina spinosa n. sp. J. Knüpfer, Freiberger ForscHft. (C), 234, 9, 10, 24, 25, pl. 4, figs. 1a-b. 1973 Piretia ? spinosa (Knüpfer); R. E. L. Schallreuter, Palaeontographica (A), 144 (1/3), 89.

1980 Piretia? spina (Knüpfer); G.Qvale, Norsk geol. Tidsskr. 60 (2), 94.

Geologisches Institut, Bergakademie Freiberg, Sachsen, German Democratic Republic; no.

45/1024, larval RV.

Type locality: Middle adit of the Iron-ore mine Gebersdorf, Thuringia; lat. 50° 32′ N, long, 11° 17′ E; limestone layer of the upper layer of the Upper Ore Horizon (Oberes Lager des Oberen Erzhorizontes =

uppermost Caradoc, zone 13), Gräfenthal series.

Geologisch-Paläontologisches Institut und Museum, University of Hamburg (GPIMH) nos. 2727 *Figured specimens:*

(\$LV: Pl. 11, 10, fig. 1), 2728 (fragmentary \$LV: Pl. 11, 10, fig. 2), 2729 (larval LV: Pl. 11, 10, fig. 3), 2730 (larval RV: Pl. 11, 12, fig. 1), 2731 (larval RV: Pl. 11, 12, fig. 2) and 2732 (larval RV: Pl. 11, 12, fig. 3). All the figured specimens are from the limestone layer of the Upper Ore Horizon of the former open-pit iron-ore mine Wittmannsgereuth, on the 'Breiten Berg' near Saalfeld, Thuringia, German Democratic Republic (H. Blumenstengel et. al., op. cit., 5-7, fig. 1); lat. 50° 39' N, long. 11° 19.5' E; coll. by the author in about 1965. All the material is coarsely silicified.

Diagnosis: As for the genus.

Remarks: Knüpfer (1968) in his original description had in hand only technomorphs. He assigned the material

to Eurychilina apparently based only on its similarity with E. multipustulosa Swain (J. Paleont., 36 (4), 727, 1962), a species now placed in synonymy with Bromidella spiveyi (Copeland, Bull, geol. Surv. Can., 347, 32, 1982). The latter species possesses an S2 sulcus developed as a pit (as in

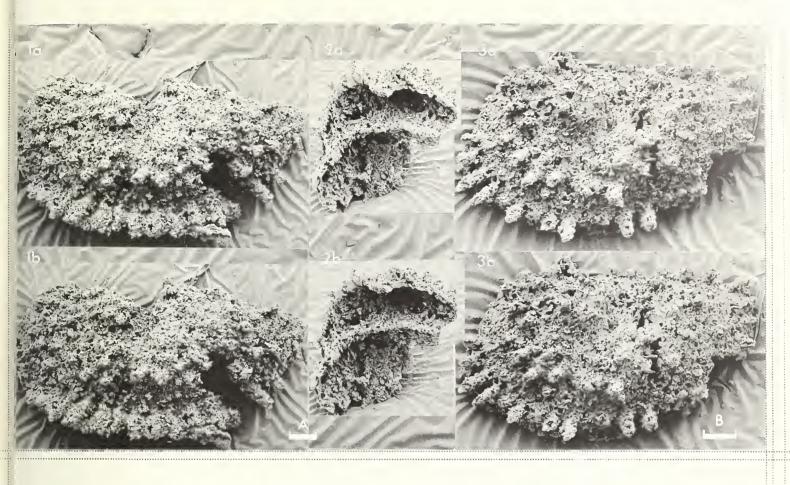

Uhakiella) and a dolon without tubules (op. cit., pl. 6, figs. 3-8, 20-22).

Known only from the type stratum in Thuringia, German Democratic Republic (localities given Distribution: above). Caradoc Series, Ordovician.

Explanation of Plate 11, 12

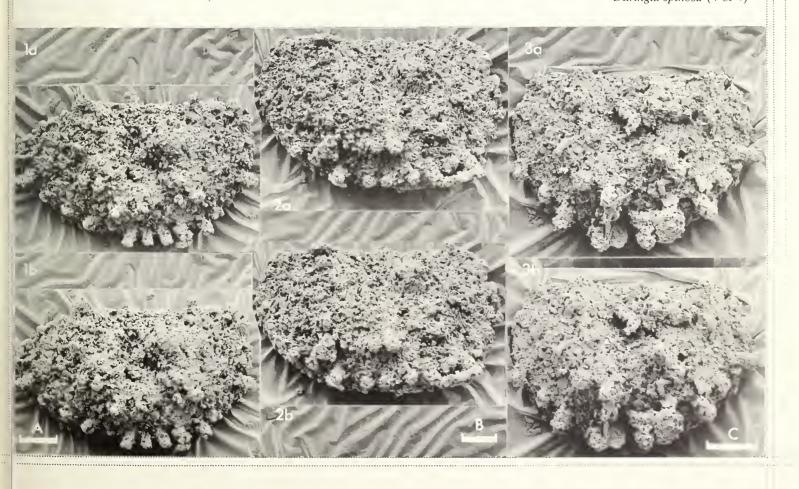

Fig. 1, posterodors. incomplete larval RV, ext. lat. (GPIMH 2730, 0.61 mm long excluding spines); fig. 2, larval RV, ext. lat. (GPIMH 2731, 0.70 mm long); fig. 3, early larval RV, ext. lat (GPIMH 2732, 0.47 mm long).

Scale A ($100 \,\mu\text{m}; \times 100$), fig. 1; scale B ($100 \,\mu\text{m}; \times 92$), fig. 2; scale C ($100 \,\mu\text{m}; \times 135$), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 12

Duringia spinosa (4 of 4)

ON DURINGIA TRIFORMOSA JONES sp. nov.

by C. R. Jones (University of Leicester, England)

Duringia triformosa sp. nov.

Holotype:

Brit. Mus. (Nat. Hist.) no. OS 12261; 9LV.

Type locality:

Old quarry about 300 m south of Cwm Agol Farm, c. 7 km west of Llandeilo, Dyfed, Wales; approx. lat. 51° 51′ N, long. 4° 05′ W (Nat. Grid. Ref. SN 56552070). Llandeilo 'Flags', Llandeilo Series,

middle Ordovician.

Derivation of name: Figured specimens: Latin, formosus, beautifully formed; alluding to the three distinct morphological forms.

Brit. Mus. (Nat. Hist.) nos. **OS** 12261 (holotype, \(\psi LV: Pl. 11, 14, fig. 5), **OS** 12260 (juv. LV: Pl. 11, 14, fig. 4), OS 12263 (6? RV: Pl. 11, 16, figs. 1, 2), OS 12262 (juv. RV: Pl. 11, 16, figs. 3, 4), OS

12264 (QLV: Pl. 11, 16, figs. 5, 6).

One specimen (QLV: Pl. 11, 14, figs. 1-3) was broken after photography. All the figured specimens are from the type locality and horizon, except for OS 12264, which comes from Capel Dewi quarry, 350 m west of Ffynnon-Dewi, c. 15.5 km west of Llandeilo, Dyfed (N.G.R. SN 47472063); Llandeilo 'Flags', lower Llandeilo, middle Ordovician.

Explanation of Plate 11, 14

Figs. 1-3, QLV (now broken, 1.30 mm long); fig. 1, ext. lat; fig. 2, ext. ant; fig. 3, ext. vent. Fig. 4, juv. LV, ext. lat. (OS 12260, 1.02 mm long). Fig. 5, \$LV, ext. lat. (holotype, **OS 12261**, 1.23 mm long). Scale A (250 μ m; × 42), figs. 1, 3; scale B (250 μ m; × 47), fig. 2; scale C (250 μ m; × 47), fig. 4; scale D (250 μ m; × 45), fig. 5.

Stereo-Atlas of Ostracod Shells 11, 15

Duringia triformosa (3 of 4)

Diagnosis: Duringia with diminutive preadductorial node. Narrow depression (= remnant S3?) from posterocentral region to dorsum. Females with weakly convex tubulose dolon, serrated distally. Tecnomorphic velum as row of spines (juveniles), or ventral flange (males?). Lateral surface spinose and granulose.

Remarks:

D. triformosa is only the second described species of the genus. The younger type-species, D. spinosa (Knüpfer, 1968) (see Schallreuter, Stereo-Atlas of Ostracod Shells, 11 (3), 9-12, 1984), from the uppermost Caradoc of Thuringia, closely resembles D. triformosa but for the presence of its dolonal spines, more convex dolon, and lack of a remnant S3. Only one complete female valve of D. spinosa is known (1.19 mm long), which falls within the large size variation displayed by D. triformosa (females from Llandeilo Series: 1.08–1.3+ mm long). Like the type-species, D. triformosa has a tubulose velum, justifying inclusion of the genus within the Eurychilinacea. However, the familial assignment of Duringia is questionable (Schallreuter, op. cit.). Schallreuter provisionally placed Duringia in the Piretellinae (Eurychilinidae) because the dolon of D. spinosa is similar but it also has dolonal spines not normally present in piretellines. D. triformosa would support this assignment as it too lacks dolonal spines. However, the sigmoidal S2 of Duringia remains strikingly opikiid-like. The recognition of a remnant S3 (?) in D. triformosa may indicate quadrilobate ancestry; its familial assignment is therefore still uncertain.

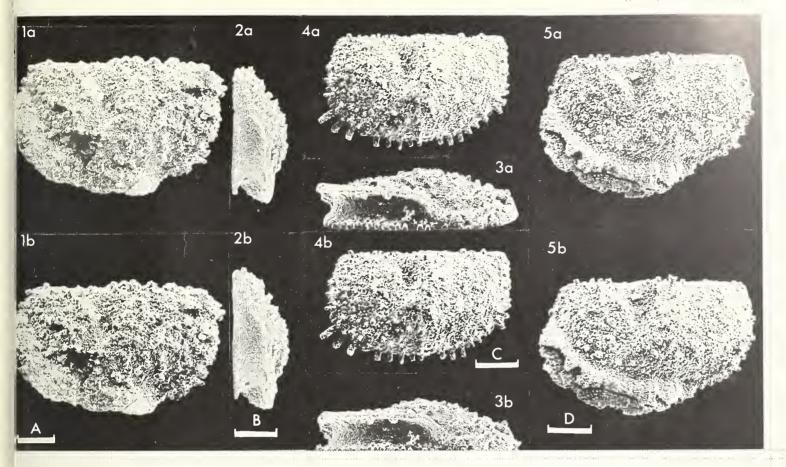

Distribution:

Llandeilo Series, and Costonian Stage, basal Caradoc Series, Dyfed, Wales and Harnagian Stage, Caradoc of Shropshire, England.

ON HAMANELLA IMPLEXA FINGER

by Kenneth L. Finger (Chevron Oil Field Research Company, La Habra, California, U.S.A.)

Genus HAMANELLA Finger, 1983

Type-species (by original designation): Hamanella implexa Finger, 1983

Diagnosis: A genus of Trachyleberididae, subovate to subtrapezoidal in lateral view with uniformly coarse and

extensive reticulum, anterior and posterior ends narrow and comparatively smooth; in dorsal view the carapace is bullet-shaped with short marginal extensions at anterior and posterior termina. Muscle scar pattern consisting of V-shaped frontal scar and vertical row of four ovate adductor scars; dorsalmost adductor scar acutely angled posteriorly to those below it. Hingement holamphidont. The inclination of the dorsalmost adductor scar suggests an affinity with the Rocaleberidini, from

Remarks: The inclination of the dorsalmost adductor scar suggests which Hamanella is otherwise morphologically distinct.

Hamanella implexa Finger, 1983

1983 Hamanella implexa sp. nov. K. L. Finger, Micropaleontology, 29 (1), 94, pl. 8, figs. 1-9, pl. 10, fig. 3.

Holotype: United States National Museum of Natural History, Washington, coll. no. USNM 332113, acar. [Paratypes: United States National Museum of Natural History coll. nos. USNM 332114, USNM 332115].

Explanation of Plate 11, 18

Figs. 1, 2, 9car. (holotype, USNM 332113, 700 μm long): fig. 1, ext. lt. lat.; fig. 2, ext. rt. lat.; fig. 3, 9RV, int. lat. (paratype, USNM 332114, 670 μm long).

Scale A (250 μ m; × 70), figs. 1–3.

Stereo-Atlas of Ostracod Shells 11, 19

Hamanella implexa (3 of 4)

Type Locality: Lower Rincon Formation, Los Sauces Creek, Santa Barbara County, California, U.S.A.; lat.

34° 22′ N, long. 119° 25′ W. Latest Zemorrian (Oligo-Miocene), *Hanzawaia crassisepta* Zone; thin-bedded calcareous mudstones interpreted by Finger (*Ibid*.) as distal-fringe turbidites deposited at

> 2000 m depth.

Figured specimens: United States National Museum coll. nos. USNM 332113 (holotype, 2 car.: Pl. 11, 18, figs. 1, 2;

Pl. 11, 20, fig. 4), USNM 332114 (paratype, \$2 RV: Pl. 11, 18. fig. 3), USNM 332115 (paratype, \$\sigma\$

car.: Pl. 11, 20, figs. 1-3). All from the type locality.

Diagnosis: As for the genus. Hamanella is presently regarded as a monotypic genus.

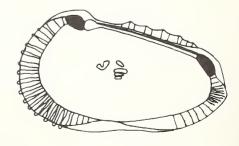

Remarks: The reversed valve overlap seen in all specimens obtained from Santa Barbara County is of

questionable taxonomic value. I have examined an unnamed form from the Saucesian (lower Miocene) of adjacent Kern County that displays normal valve overlap and is otherwise not too

dissimilar from H. implexa.

Distribution: Currently known only from the latest Zemorrian (Oligo-Miocene) of the Santa Barbara Embay-

ment, California, U.S.A.

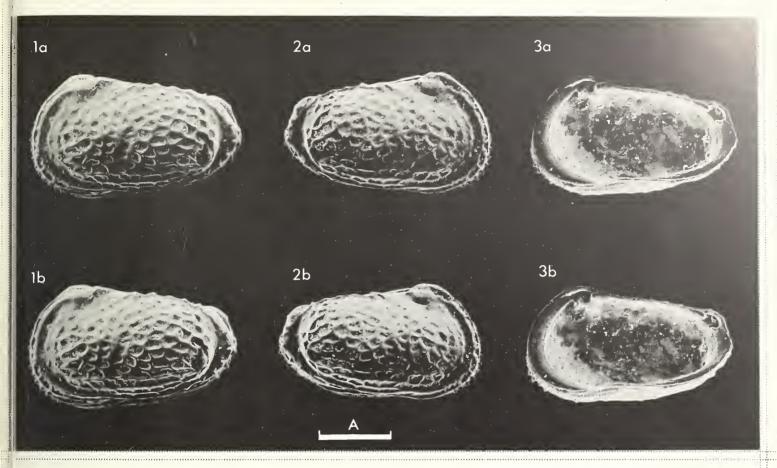

Text-fig. 1 Composite drawing of H. implexa, $\Re RV$, internal view ($\times 70$).

ON SAGMATOCYTHERE PARACERCINATA WHATLEY & MAYBURY sp. nov.

by R. C. Whatley & C. Maybury (University College of Wales, Aberystwyth)

Sagmatocythere paracercinata sp. nov.

Holotype: Brit. Mus. (Nat. Hist.) no. OS 12116, PRV.

[Paratypes: Brit. Mus. (Nat. Hist.) nos. **OS 12117 - OS 12120**].

Type locality: Blue Clay, Sample No. 29, N W corner Vicarage Pit, St. Erth, Cornwall, England (Nat. Grid Ref.

SW 556352); Upper Pliocene

Derivation of name: Latin, reflecting the close morphological and possible ancestral relationship of this species to

Sagmatocythere cercinata (Bonaduce, Masoli & Pugliese, 1976) (Pubbl. Staz. zool. Napoli, 40,

394–395, pl. 11, figs. 6–9) from the Recent of the Gulf of Aqaba, Red Sea.

Figured specimens: Brit. Mus. (Nat. Hist.) nos. OS 12116 (holotype, \$\partial RV: Pl. 11, 22, fig. 1), OS 12117 (\$\sigma LV: Pl. 11,

22, fig. 2), OS 12118 (&RV: Pl. 11, 22, fig. 3), OS 12120 (&RV: Pl. 11, 24, fig. 1, 3, 4), OS 12119

(&LV: Pl. 11, 24, fig. 2). All from the type locality and type horizon.

Explanation of Plate 11, 22

Fig. 1, \$\text{RV, ext. lat. (holotype, OS 12116, 400 μm long); fig. 2, σLV, ext. lat. (paratype, OS 12117, 450 μm long); fig. 3, σRV, ext. lat. (paratype, OS 12118, 440 μm long). Scale A (100 μm; × 140), figs. 1–3.

Stereo-Atlas of Ostracod Shells 11, 23

Sagmatocythere paracercinata (3 of 4)

Diagnosis: A species of Sagmatocythere with a prominent alar process overhanging the ventral margin.

Reticulae irregular in the alar region and immediately anterior of the eye spot. Free marginal areas

flat and without reticulation.

Remarks: The close similarity between S. cercinata and the new species has already been indicated, the major

differences being those of size and ornamentation; S. paracercinata is larger (S. cercinata, 360 µm

long) and has relatively and absolutely smaller fossae.

The Loxoconchidae are very diverse in the Upper Pliocene of N W France and St. Erth with 75 species/subspecies belonging to 12 genera. *Sagmatocythere*, represented by 18 species/subspecies is the most diverse genus of the family. *S. paracercinata* is abundant in the St. Erth beds (204 adult valves and 530 juvenile valves) but only one male right valve and two juvenile valves have been

recovered from France.

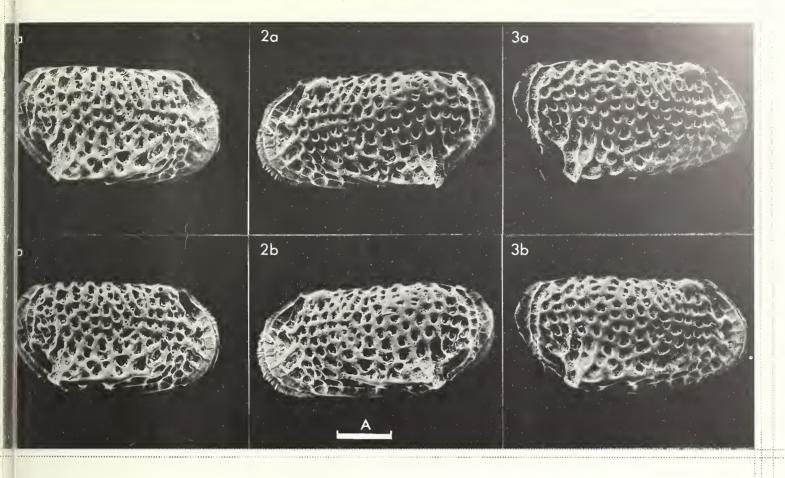

Distribution: Upper Pliocene; St. Erth, Cornwall, England; Le Temple du Cerisier, S W of Rennes and from

Borehole 1549 at Saint-Jean-la-Poterie, S W of Redon, N W France.

ON SAGMATOCYTHERE PSEUDOMULTIFORA MAYBURY & WHATLEY sp. nov.

by C. Maybury & R. C. Whatley (University College of Wales, Aberystwyth)

Sagmatocythere pseudomultifora sp. nov.

?1981 Loxoconcha sp.; H. Hagn, H. Malz & E. Martini, Geologica bav., 82, 270, pl. 2, figs. 1, 2.

Holotype: Brit. Mus. (Nat. Hist.) no. OS 12121, PRV.

[Paratypes: Brit. Mus. (Nat. Hist.) nos. **OS** 12122 - **OS** 12126].

Type locality: Blue Clay, Sample No. 29, N W corner Vicarage Pit, St. Erth, Cornwall, England (Nat. Grid Ref.

SW 556352); Upper Pliocene.

Derivation of name: Latin, reflecting its close similarity to Sagmatocythere multifora (Norman, 1865) (In: G.S. Brady,

Nat. Hist. Trans. Northumberland & Durham, 1, 18–19, pl. 6, figs. 13–16).

Figured specimens: Brit. Mus. (Nat. Hist.) nos. OS 12121 (holotype, \$\forall RV: Pl. 11, 26, fig. 1), OS 12122 (\$\sigma LV: Pl. 11,

26, fig. 2), **OS 12123** (σ RV: Pl. 11, 26, fig. 3), **OS 12124** (ΨLV: Pl. 11, 28, fig. 1), **OS 12125** (Ψcar.: Pl. 11, 28, fig. 2), **OS 12126** (σ car.: Pl. 11, 28, fig. 3). All from the type locality and horizon.

Explanation of Plate 11, 26

Fig. 1, \$\text{PRV}, ext. lat. (holotype, OS 12121, 460 μm long); fig. 2, \$\sigmu LV\$, ext. lat. (paratype, OS 12122, 510 μm long); fig. 3, \$\sigmu RV\$, ext. lat. (paratype, OS 12123, 510 μm long). Scale A (100 μm; × 125), figs. 1–3.

Stereo-Atlas of Ostracod Shells 11, 27

Distribution:

Sagmatocythere pseudomultifora (3 of 4)

Diagnosis: A species of Sagmatocythere with an inconspicuous alar process and strong reticulation, the fossae being particularly well-developed in the posterior and alar regions. A wide frill-like flange surrounds

the free marginal areas which are strongly laterally compressed.

Remarks: This species is probably synonymous with S. sp. (Hagn, Malz & Martini, 1981, op. cit.); but the small illustrations and lack of a formal description for this species render this possibility tenuous.

S. pseudomultifora resembles S. multifora (Norman) in shape and gross morphology of ornament, but differs in size (Norman's species is smaller, only $390-395 \,\mu\mathrm{m}$ long) and in its possession of a more regular reticulum and more strongly developed and acute alae. The two species constitute what are in the authors' opinion more typical members of the genus than the type-species,

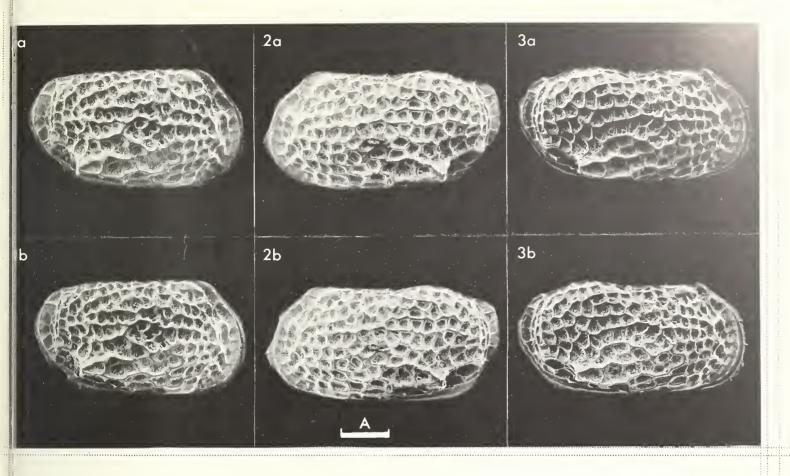

S. napoliana (Puri, 1963) (Athersuch, Stereo-Atlas of Ostracod Shells, 3 (21), 117-124, 1976).

S. pseudomultifora occurs abundantly in the Upper Pliocene St. Erth beds and is also present in the deposits of three localities in N W France of Redonian age: Le Bosq d'Aubigny, Le Bosq d'Aubigny (Manche) and Le Temple du Cerisier. See J.-P. Margerel, Les Foraminifères du Redonien. Systématique, Répartition stratigraphique, Paléoécologie, Nantes I, 1–207, 1968, for geographical and stratigraphical details of the French localities. The species probably also occurs in the Miocene of

S Germany (Hagn, Malz & Martini, op. cit.).

ON CYTHERIDEA (CYTHERIDEA) MUELLERI MUELLERI (V. MÜNSTER)

by Roseline H. Weiss (Geological Institute, University of Cologne, Germany)

Genus CYTHERIDEA Bosquet, 1852 Subgenus CYTHERIDEA Bosquet, 1852

Type-species (by original designation): Cythere Müllerii v. Münster, 1830

Diagnosis:

The typical subgenus of *Cytheridea* with a special type of hinge: left valve with terminal loculate sockets and a somewhat oblique median element, the anterior part of which is elevated while the posterior part is depressed with respect to the dorsal margin.

Cytheridea (Cytheridea) muelleri muelleri (v. Münster, 1830)

Table 1. Measurements on specimens (N = no. of specimens; \bar{x} = mean; L = length without marginal spines; H = height; W = width); A = valves, B = carapaces.

Diagnosis:

Carapace ovate to subquadrangular in dorsal view; subtrapezoidal in lateral view, anterior end obliquely rounded, posterior end obliquely truncated, narrowly rounded posteroventrally. Dorsal margin straight to slightly convex; ventral margin straight (left valve) to very slightly concave in posterior half (right valve). Surface of the valves pitted. Along the free margin the pits are arranged in subparallel rows. Anterior end with marginal denticulations (right valve: up to 15; left valve: 7). Posterior end of the right valve provided with three marginal spines. Anteriorly and posteroventrally narrow vestibules are present.

Explanation of Plate 11, 34

Fig. 1, o'LV, ext. lat. (GIK 932–1008, 825 μ m long); fig. 2, o'RV, ext. lat. (GIK 932–1713, 813 μ m long). Length includes marginal spines Both valves are from the same carapace. Scale A (100 μ m; × 113), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 35

Cytheridea muelleri muelleri (7 of 8)

Remarks

Sexual dimorphism pronounced, the males being lower and, in dorsal view, narrower than the females, but of the same length. Differences discussed in detail by Weiss (1983b, op. cit.).

The hinge of each valve is divided into three elements. The terminal elements are dentate plates (right valve) or loculate sockets (left valve); the median element is oblique with respect to the dorsal margin and the left valve provided with different types of toothlets.

Normal pores are moderately numerous, scattered and of the sieve – type. The sieve – plates are perforated (approx. 6–12 small pores along the diameter); the setal perforation is eccentric. Marginal pore – canals are numerous (approx. 40 anteriorly). They reach the shell surface distally of the flange in two parallel lines. Occasionally a lip is developed around the openings. Line of concrescence and inner margin are slightly separated anteriorly and posteroventrally.

The investigated specimens from Tönisberg agree absolutely with Goerlich's material from the type-locality of Astrup. Many of the previous records described under this name by various authors (Reuss 1850, Bosquet 1852, Jones 1857, Speyer 1863, Stanceva 1962, Faupel 1975) represent different species.

Distribution:

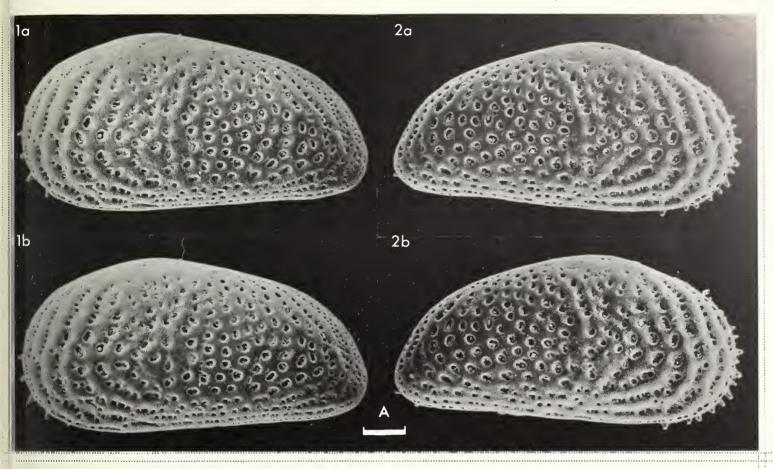

Upper Oligocene: Astrup near Osnabrück, Germany (v. Münster 1830, Lienenklaus 1894, Stephenson 1936, Goerlich 1952, Oertli & Key 1955, Oertli 1956, Triebel 1958, op. cit.); Shaft Rossenray (Lower Rhine Basin), Germany (Goerlich 1958, op. cit.); Shaft Tönisberg (Lower Rhine Basin), Germany (Weiss 1983b, op. cit.); Niedersachsen (borings), Germany (Uffenorde 1980, 1981, op. cit.).

Cytheridea muelleri muelleri (8 of 8)

ON CYTHERIDEA (CYTHERIDEA) MUELLERI TOENISBERGENSIS WEISS

by Roseline H. Weiss (Geological Institute, University of Cologne, Germany)

Cytheridea (Cytheridea) muelleri toenisbergensis Weiss, 1983

1983b Cytheridea (Cytheridea) muelleri toenisbergensis subsp. nov. R. H. Weiss, Palaeontographica, Abt. A, 182 (4-6), 94, pl. 22, figs. 1-10, text-fig. 12.

Holotype: Geological Institute, University of Cologne, Germany, GIK 932-1722, 9 car.

[Paratypes: Geological Institute, University at Cologne, GIK 932: 1709-1712, 1714-1719,

1722-1727].

Type locality: Shaft Tönisberg near Krefeld, Germany (German Nat. Grid Ref.: R 34033, H 97555; long. b° 29' E,

lat. 51° 25′ N).

Type horizon: Depth range 54.2-55.5 m; Upper Oligocene; Sphenolithus ciperoensis zone (NP25) according to

Benedek & Müller (*Neues Jb. Geol. Paläont.*, Mh., 1974, 388§); fine sand (grain size 0.2–0.06 mm = 92.5%) according to Kempf (*Niederrhein*, 35, fig. 2, 1968); shallow marine (5–20 m water depth)

according to Goerlich (Fortschr. Geol. Rheinld. Westf., 1, 220, 1958).

Figured specimens: Geological Institute, University of Cologne, nos. 932-1709 (\$RV: Pl. 11, 44 fig. 1), 932-1714

(\$LV: Pl. 11, 42, fig. 1), 932–1716 (\$\delta\$LV: Pl. 11. 42, fig. 2), 932–117 (\$\delta\$RV: Pl. 11, 44, fig. 2), 932–1718 (\$\delta\$RV; Pl. 11, 40, fig. 2), 932–1722 (\$\delta\$car.; Pl. 11, 38, fig. 1), 932–1723 (\$\delta\$car.; Pl. 11,

38, fig. 2), **932–1724** (of car.: Pl. **11**, 40, fig. 1).

Explanation of Plate 11, 38

Fig. 1, \Im car., ext. dors. (holotype, GIK 932–1722, 775 μ m long); fig. 2, \Im car., ext. dors. (GIK 932–1723, 763 μ m long). Scale A (100 μ m; × 122), figs. 1, 2.

tereo-Atlas of Ostracod Shells 11, 40

Cytheridea muelleri toenisbergensis (4 of 8)

Diagnosis: A subspecies of Cytheridea (Cytheridea) muelleri with anterior end of carapace subrectangular in

dorsal view.

Remarks: Sexual dimorphism pronounced, the males being lower and, in dorsal view, narrower than the females, but of the same length. Differences discussed in detail by Weiss (1983b, op. cit.).

In every respect, the internal features of the subspecies are very similar to the nominate subspecies *Cytheridea* (C.) muelleri muelleri (v. Münster) from the Upper Oligocene of Astrup (see Weiss, Stereo-Atlas of Ostracod Shells 11, 29–36, 1984). Only the median hinge element (left valve) sometimes shows small differences in the shape of the toothlets.

The main difference is the subrectangular shape of the anterior end of the carapace in dorsal view. Minor differences are observable at the posterior end of the right valves. This end is somewhat more narrowly rounded and – as well preserved specimens show – provided with four marginal spines instead of three. Similar to the nominate subspecies the central muscle scars consist of a row of four undivided adductor muscle scars (the lower three are generally more elongate than the upper one), a well-developed fulcral point and a frontal scar which is split into a larger posterior and a smaller anterior part. The frontal scar occasionally shows a tendency to become V-shaped. There are also two mandibular scars: the upper scar is more elongate and larger than the lower one (Text-fig. 1).

Explanation of Plate 11, 42

Fig. 1, \$\Pmathbb{L}V\, int. lat. (GIK 932–1714; 813 μm long); fig. 2, \$\sigma LV\, int. lat. (GIK 932–1716; 800 μm long). Length includes marginal spines.

Scale A (100 μ m; × 117), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 43

Remarks: (contd.)

Cytheridea (C.) muelleri truncatula Goerlich, 1953 (Senckenbergiana, 34, 131, pl. 1, figs. 6 a-c) from the Upper Oligocene of the Bavarian Molasse differs in being shorter and having a different carapace outline in lateral and dorsal view. The posterior end of the right valve is provided with one marginal tooth only.

Cytheridea Mulleri, var. B acuminata Bosquet, 1852 (Mém. cour. mém. sav. étrang., 24, 39, pl. 2, figs. 4a-f) from the Tortonian of the Vienna Basin was considered to be a separate species by Goerlich (1953).

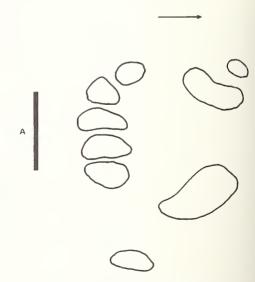

Cytheridea müllerii, var. helvetica Lienenklaus, 1896 (Abh. schweiz. Paläont. Ges., 22, 26, pl. 2, fig. 6) from the Upper Oligocene of the Bavarian Molasse has been linked with the genus Haplocytheridea by Goerlich in 1953.

The Upper Oligocene Cytheridea muelleri, var. rhenana Lienenklaus, 1905 (Ber. senckenb. naturf. Ges., 36, 39) from the Mainz Basin was transfered to Hemicyprideis by Malz & Triebel in 1970.

Table 1. Measurements on specimens (N = no. of specimens; \overline{x} = mean; L = length without marginal spines; H = height; W = width); A = valves, B = carapaces.

Diagnosis

Carapace ovate with somewhat more narrowly rounded posterior end in dorsal view; in lateral view subtrapezoidal, anterior end obliquely rounded, posterior end obliquely truncated and narrowly rounded posteroventrally. Dorsal margin straight to slight convex; ventral margin straight (left valve) to considerably concave in posterior half (right valve) Surface of the valves pitted. Along the free margin the pits are arranged in subparallel rows. Anterior end of both valves with seven marginal denticulations. Posterior end of the right valve provided with three marginal spines. Anteriorly and posteroventrally narrow vestibules are present.

Explanation of Plate 11, 50

Fig. 1, QLV, ext. lat. (GIK 932–1731; 850 μm long); fig. 2, σLV, ext. lat. (GIK 932–1729; 900 μm long). Length includes marginal spines. Pl. 11, 48, fig. 2 and Pl. 11, 50, fig. 2 represent both valves of a single carapace. Scale A (100 μm; × 105), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 51

Cytheridea pernota (7 of 8)

Remarks.

Sexual dimorphism pronounced. Shell morphotype B (presumed male) more elongate and in dorsal view narrower than morphotype A. Differences discussed in detail by Weiss (1938b, op. cit.).

In respect of internal features, Cytheridea (Cytheridea) pernota is very similar to the type-

species Cytheridea (C.) muelleri (v. Münster, 1830).

Minor differences are observable in the shape of the toothlets of the median hinge element (left valve) and in the lower mandibular scar. The latter is occasionally divided into two separate scars. Unfortunately the small number of specimens at my disposal is not sufficient to give general conclusions on these differences.

Stereo-Atlas of Ostracod Shells 11, 55

Paracytheridea cuneiformis (3 of 6)

Diagnosis:

A species of *Paracytheridea* with very subdued ornament, the alar expansions being reduced to inconspicuous swellings. The most prominent ornamental features are two ribs, the first running obliquely from the eye-spot to the antero-ventral margin where it forms an acute angle with the second which runs sub-marginally back to the anterior of the two alar swellings.

Remarks:

A careful comparison of *P.cuneiformis* (type-species of *Xenocythere* Sars, 1925) with Müller's original description and illustrations of the type-species of *Paracytheridea* (*P.depressa* G. W. Müller, 1894) shows that the two are almost indistinguishable except by the differential development of their carapace ornament. The appendages of the two species are virtually identical, including antennulae with five articulated podomeres and antennae with two terminal setae, one long and chelate, the other slender and reduced. Both species have an antimerodont/weak entomodont hinge, and there are close similarities in their carapace shape and basic pattern of ornament. Although the reduced ornament of *P.cuneiformis* clearly separates it from strongly alate Mediterranean species of *Paracytheridea*, intermediate forms have been described from elsewhere; see for example, *P.cronini* Hazel, 1983 and *P.mucra* Edwards, 1944, both illustrated by Hazel (*Smithsonian Contributions to Paleobiology*, no. 53, pl. 28, figs. 1–2, pl. 29, figs. 1–2, 1983). We therefore conclude that *Xenocythere* is a junior synonym of *Paracytheridea*.

We have been unable to trace the references to Reuss and Speyer by Brady (1868, op.cit.) and Sars (1925, op.cit.) respectively as having previously assigned the name *Cythere ventricosa* to other ostracod species. Nevertheless the two earlier uses of this name by Bosquet and Kirkby cited in the synonymy herein clearly demonstrate that the name *C.ventricosa* Sars, 1866 is preoccupied.

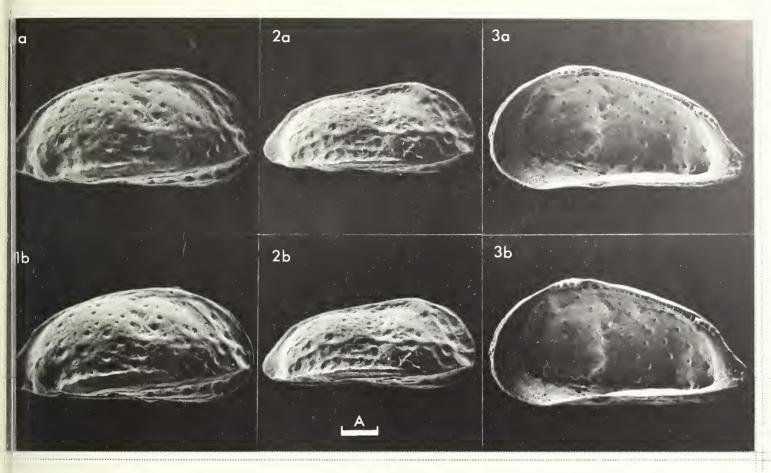

Distribution:

Recent: marine, sublittoral (to depths of around 20 m), rarely littoral; coasts of Scandinavia, British Isles and N W Europe.

Pleistocene: British Isles.

ON ATJEHELLA KINGMAI KEIJ

by Manzoor Hasan (University of Leicester, England)

Atjehella kingmai Keij, 1979

1979 Atjehella kingmai sp. nov. A. J. Keij, Proc. K. ned. Akad. Wet., Ser. B, 82 (4), 458, pl. 2, figs. 1-14.

Holotype: (not figured herein). Geological Institute of the State University of Utrecht, the Netherlands, coll.

no. T 333; ♀LV.

Type locality: South China Sea at 3°57′ N, 113°02′ 30″ E (sample Ms 7200); Recent; depth 35 m.

Figured specimens: Brit. Mus. (Nat. Hist.) nos. OS 10148 (SRV: Pl. 11, 60, fig. 1; Pl. 11, 62, figs. 1-3), OS 10149

(PRV: Pl. 11, 60, fig. 2; **OS 10150** (& LV: Pl. 11, 60, fig. 3), **OS 10152** (& RV: Text-fig. 1). All from Darvel Bay, Malaysia, coll. HMS Dampier. **OS 10148, OS 10149** and **OS 10150** are from lat. 04°55.1′N, long. 118°25.5′E; coll. 1962; depth 14 fathoms (26 m). **OS 10152** is from lat.

04° 40.2′ N, long. 118° 44.0′ E; coll. 1965; depth 40 fathoms (73 m).

Diagnosis: Species of Atjehella with well-developed reticulation of the shell surface spreading from median to

mid-dorsal region. Three peripheral ridges in anterior region. Sieve-plates sparsely scattered over

shell surface.

Explanation of Plate 11, 60

Fig. 1,σRV, ext. lat. (OS 10148, 512 μm long); fig. 2,9RV, ext. lat. (OS 10149, 480 μm long); fig. 3,σLV, ext. lat. (OS 10150, 439 μm long).

Scale A (150 μ m; × 131), fig. 1; scale B (150 μ m; × 135), fig. 2; scale C (150 μ m; × 143), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 61

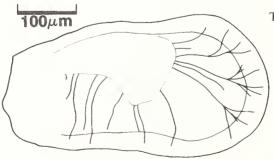

Atjehella kingmai (3 of 4)

Remarks:

So far in the literature the presence of sieve-plates in Atjehella has not been mentioned, but they do exist and are especially prominent in some specimens of A.kingmai from Darvel Bay. These sieve-plates are generally sunk below the surface level of the shell and have central openings. Keij (op. cit., 1979) has mentioned "Within Atjehella kingmai n.sp. we observed Indonesian populations along the East coast of Kalimantan which possess a more pronounced intercarinal ornamentation than normally found in the South China Sea". In the present material specimens both with and without pronounced intercarinal ornamentation have been observed.

Distribution:

Known from the Recent of South China Sea, beach of Seria in Brunei, beach of Dent Peninsula, Java Sea, harbour of Merak in West Java, Balikpapan Bay and Darvel Bay (herein).

Text-fig. 1. Marginal pore canals of *Atjehella kingmai* Keij, & RV (OS 10152), drawn in transmitted light.

Fig. 1,σ'LV, ext. lat. (OS 10142, 414 μm long); fig. 2, \$\frac{9}{4}\$RV, ext. lat. (OS 10143, 341 μm long); fig. 3,σ'LV, ext. lat. (OS 10144, 390 μm long).

Scale A ($100 \,\mu\text{m}; \times 157$), fig. 1; scale B ($100 \,\mu\text{m}; \times 199$), fig. 2; scale C ($100 \,\mu\text{m}; \times 159$), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 65

Cytherelloidea bonanzaensis (3 of 4)

Diagnosis: Species of Cytherelloidea with a distinctive ornament consisting of circular fossae connected by a

reticulate pattern of low muri which is less prominent in the median and dorsomedian regions. The sola between the muri are foveolate. Scattered conjunctive normal pores present. Muscle-scar area

forms a well-marked depression on the external surface of the valve.

Remarks: The surface ornamentation of C. bonanzaensis Keij is unique among Cytherelloidea species.

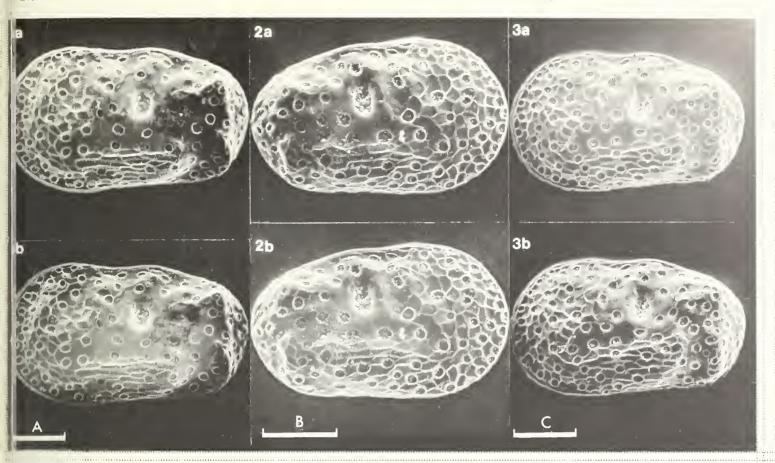

Distribution: Recent, marine: off Sabah and Brunei in South China Sea (Keij, 1964); Darvel Bay, Malaysia

(herein).

Explanation of Plate 11, 66

Figs. 1–3, o'LV, ext. lat. (OS 10144): fig. 1, ant. dors. region showing fossae and reticulation; fig. 2, detail of circular fossa from fig. 1; fig. 3, detail of external depression in muscle-scar region.

Cytherelloidea bonanzaensis (4 of 4)

ON OGMOCONCHA EOCONTRACTULA PARK sp. nov.

by Se-Moon Park (University College London)

Ogmoconcha eocontractula sp. nov.

British Geological Survey MPK 4134, carapace. Holotype:

[Paratypes: BGS MPK 4135 - BGS MPK 4137].

528.00 m-528.50 m depth below surface, Trunch Borehole, Norfolk, England; lat. 52°50' N, *Type locality:*

long. 1°23' E. National Grid Reference: TG 2937 3450. Mudstone, medium brownish grey; Lower

Pliensbachian, Jurassic.

From the Greek eos, early; with reference to the species O. contractula. Derivation of name:

British Geological Survey nos. MPK 4134 (holotype, car.: Pl. 11, 68, fig. 2; Pl. 11, 70, fig. 1), MPK Figured specimens:

4135 (LV: Pl. 11, 68, fig. 1), MPK 4136 (RV: Pl. 11, 70, fig. 4), MPK 4137 (LV: Pl. 11, 70, figs. 2, 3).

All material from the Trunch Borehole, Norfolk, England (see type locality).

A species of Ogmoconcha similar to O. contractula Triebel but distinguished by its larger size and a Diagnosis:

more elongate, triangular lateral outline in which the position of greatest height is distinctly anterior

of mid-length; ventral margin of left valve broadly convex in outline.

Specific differentiation within Ogmoconcha and the allied Ogmoconchella is difficult, but comparison Remarks:

of the present material with the type specimens of O. contractula Triebel (Senckenbergiana, 23, 378, 1941) in the Senckenberg Museum, Frankfurt, demonstrates that two species are present. O. eocontractula is larger (adults 0.840-0.910 mm long, 0.560-0.630 mm high) than O. contractula (0.800-0.840 mm long; holotype = X/E1249). The former differs markedly in lateral shape of each

valve, as indicated in the diagnosis, and the two species also differ in range.

Explanation of Plate 11, 68

Fig. 1, LV, ext. lat. (MPK 4135, 880 μ m long); fig. 2, car., ext. rt. lat. (holotype, MPK 4134, 910 μ m long). Scale A (200 μ m; × 69), fig. 1; scale B (200 μ m; × 66), fig. 2.

Stereo-Atlas of Ostracod Shells 11, 69

Ogmoconcha eocontractula (3 of 4)

Remarks (contd.):

Triebel recorded O. contractula from Lias delta (Upper Pliensbachian) in the North German Hambühren WA-2 boring at depths of 495–503 m. Specimens identical with O. eocontractula, deposited in the Senckenberg Museum, Frankfurt, occur in Hambühren WA-2 at depths of 509-607 m. O. eocontractula is apparently an ancestor of O. contractula.

O. eocontractula resembles Ogmoconcha amalthei (Quenstedt, Der Jura, Tubingen, 1858) in outline, but when compared with the material deposited in the Senckenberg Museum, Frankfurt, they differ in several respects. The latter is highly arched antero-dorsally, whereas the former is somewhat rounded dorsally. The surface of O. eocontractula is punctate, whereas that of O. amalthei is smooth, and there is a swollen ventral rim (ventral depression) in O. amalthei which is absent in O. eocontractula.

O. eocontractula is also comparable with Ogmoconcha "amalthei form A" of Michelsen (Geol. Surv. Denmark, 104, 228, 1975) from Denmark, deposited in the Geological Survey of Denmark, Copenhagen (DGU-1973-OM-26). There are fine punctae on the surface in both species, but the posterior margin of the latter is distinctly elongate. Michelsen's species is closely allied to O. eocontractula and may be a different subspecies. Michelsen recorded O. "amalthei form A" from the Lower Pliensbachian, where O. eocontractula also occurs. No O. eocontractula s.s. have been recognised in Michelsen's Danish material.

Distribution: 108 carapaces and 323 valves, adults and instars, from the Trunch Borehole (563.50 m – 525.50 m)

England; the De Lutte boring No. 3 (260 m-198 m) and the Oldenzaal boring No. 1 (427 m-333 m), The Netherlands; Hambühren WA-2 boring (509 m-607 m depth), German Federal Republic; all

levels are Lower Pliensbachian, Jurassic.

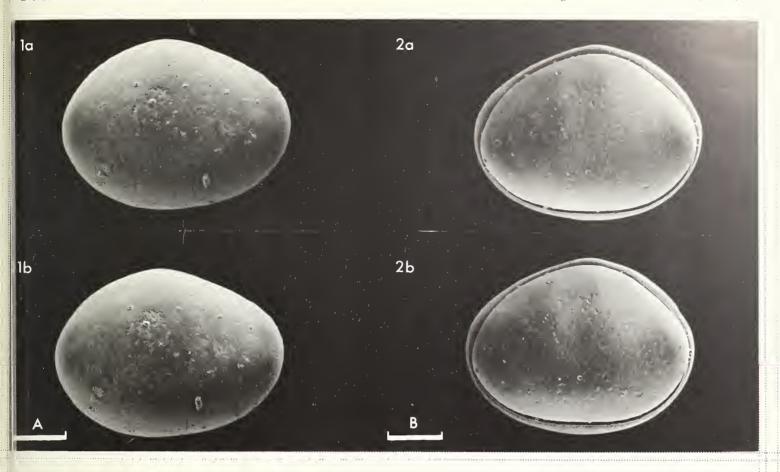

The Director of the British Geological Survey (BGS) has approved the use of BGS material in this Acknowledgements: work. The assistance of Dr. H. Malz and Dr. O. Michelsen is gratefully acknowledged. The Univer-

sity of London Central Research Fund generously provided travelling expenses.

ON DONMACYTHERE DAMOTTAE (COLIN)

by J. P. Colin

(Esso Production Research-European Laboratory, Bègles, France)

Genus DONMACYTHERE Gründel, 1976

Type-species: Hazelina? damottae Colin, 1974

Diagnosis: General outline and sculpture similar to the genus Mandocythere Gründel, 1964. Surface of valves

smooth. Well developed median ridge, obliquely oriented, not connected with the dorsal ridge. Anterior marginal and ventral ridge in continuity. Hinge amphidont. Marginal zones moderately wide (1/10 of length), without vestibulum. More than 35 anterior marginal pore canals, sinuous and

thickened in their median part. Sexual dimorphism well marked, with males more elongated.

Remarks: This genus was originally described as a subgenus of Mandocythere by Gründel, 1976. Veenia inferangulata Donze, 1972 (Rev. esp. Micropaleontol., 4, 368, pl. 2, figs. 3–9), from the Cenomanian

of the Southern Alps (SE France), was also placed in this genus by Gründel. Weaver (*Palaeontogr. Soc.* Monogr., 135, 51, 1982) doubts this assignation on the basis of the observation of "variably

crenulate hinge teeth".

Explanation of Plate 11, 72

Fig. 1, \$\text{PRV}, ext. lat. (14139-40, 765 \(\mu\) long); fig. 2, σ'LV, ext. lat. (14141-42, 800 \(\mu\) long); fig. 3, \$\text{LV}, ext. lat. (14143-44, 740 \(\mu\) long).

Scale A (200 μ m; × 81), figs. 1, 3; scale B (200 μ m; × 68), fig. 2.

Stereo-Atlas of Ostracod Shells 11, 73

Donmacythere damottae (3 of 4)

Donmacythere damottae (Colin, 1974)

1974 *Hazelina? damottae* n. sp. J. P. Colin, *Géobios*, 7, 26–27, pl. 8, figs. 9–12.

1976 Mandocythere (Donmacythere) damottae (Colin); J. Gründel, Z. geol. Wiss. Berlin, 4, 1297.

1980 Hazelina damottae Colin; J. F. Babinot, Trav. Lab. Géol. Hist. Univ., Provence, 10, 136, pl. 20, figs. 11-13.

Holotype: Unnumbered left valve, deposited in the collections of the Laboratoire de Micropaléontologie,

Université Pierre et Marie Curie, Paris.

Type-locality: Le Fournet, village of Berbiguières, near St Cyprien, Dordogne, S W France: approx. lat. 44° 50′ N,

long. 1°03′ W. Late Cenomanian, Cretaceous.

Figured specimens: Esso Production Research-European Laboratory nos. EPR-E 14135–36 (9 car.: Pl. 11, 74, fig. 2),

14137-38 (of car.: Pl. 11, 74, fig. 3) 14139-40 (PRV: Pl. 11, 72, fig. 1), 14141-42 (of LV: Pl. 11, 72,

fig. 2), 14143-44 (\$LV: Pl. 11, 72, fig. 3), 114145-46 (o'LV: Pl. 11, 74, fig. 1).

All the specimens are from the late Cenomanian of the type-locality: marls with very rich

ostracod faunas and foraminifera (Thomasinella punica, Daxia cenomana).

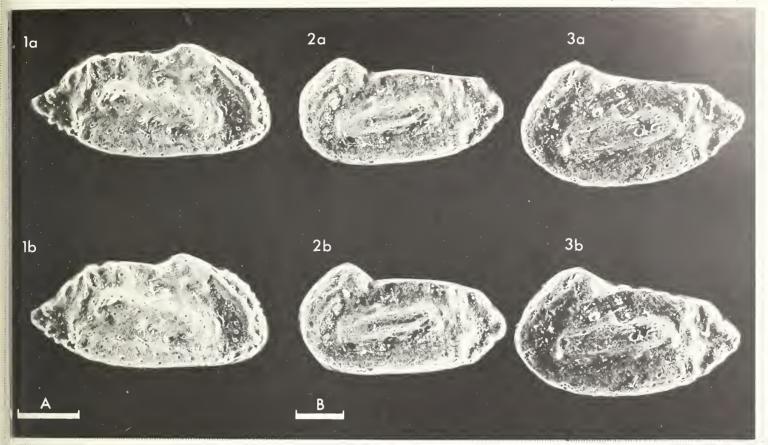

Diagnosis: As for the genus.

Distribution: Late Cenomanian of SW and SE France and Spain.

Instructions to Authors

Contributions illustrated by scanning electron micrographs of Ostracoda in stereo-pairs are invited. Format should follow the style set by the majority of papers in this issue. Descriptive matter apart from illustrations should be cut to a minimum; preferably each plate should be accompanied by one page of text only. Blanks to aid in mounting figures for plates may be obtained from any one of the Editors or Editorial Board. Completed papers should be sent to Dr David J. Siveter.

The front cover shows a female left valve of Hemicythere villosa (Sars, 1866)

ON LEOCYTHERIDEA POLLETI KEEN gen. et sp. nov.

by M. C. Keen (University of Glasgow, Scotland)

Genus LEOCYTHERIDEA gen. nov.

Type-species: Leocytheridea polleti sp. nov.

Derivation of name:

Diagnosis:

Latin Leo, lion, referring to the "mountains of the Lion", the origin of the name Sierra Leone. Ovate lateral outline, left valve larger than right, males more elongate than females; surface smooth or pitted with prominent sieve-type normal pore canals; hinge antimerodont; inner margin broad and irregular, with a prominent anterior indentation, small anterior vestibule, and long sinuous radial pore canals; central muscle scars consist of vertical row of four scars with a single frontal scar.

Remarks:

The inner margin and the sinuous radial pore canals are very similar to those of Cytheretta, but the hinge is entirely different. The hinge is somewhat similar to many genera of the Cytherideinae, such as Clithrocytheridea, and in general lateral outline the valves are similar to such genera as Cyamocytheridea, Clithrocytheridea, and Oyocytheridea. The anterior vestibule is similar to that of Cyamocytheridea. The hinge is similar to that of Hemikrithe, which also has an irregular inner margin; Hemikrithe differs in lateral outline, central muscle scars, and type of radial pore canals. Some species of *Parakrithe* have a similar appearance, but differ in the hinge and type of radial pore canals.

Explanation of Plate 11, 76

Figs. 1, 3, ♀ LV (OS12287, 680μm long): fig. 1 ext. lat.; fig. 3 normal pore canal with sieve-plate destroyed; fig. 2, ♂ LV, ext. lat. (specimen destroyed, 700μm long); fig. 4, δ RV (OS12289), normal pore canal with sieve-plate intact. All paratypes. Scale A (100 μ m; ×107); fig. 1; scale B (100 μ m; ×101), fig. 2; scale C (5 μ m; ×2500), fig. 3; scale D (5 μ m; ×2000), fig. 4.

Stereo-Atlas of Ostracod Shells 11, 77

Leocytheridea polleti (3 of 8)

Remarks (contd.): Leocytheridea is placed in the Cytherideidae on account of lateral shape and ornamentation, hinge, and central muscle scars. The irregular inner margin and sinuous radial pore canals are different from other members of the subfamily Cytherideinae, while the muscle scars and radial pore canals differ from the Krithinae. There is therefore considerable doubt as to which family and subfamily the new genus should be assigned.

Leocytheridea polleti sp. nov.

Holotype:

British Museum (Nat. Hist.) no. OS12288; ♀ RV.

Type locality:

Tertiary (Oligocene?) part of the Bullom Series from borehole SLBH9 near Hastings, Sierra Leone (Baker, C. D. & Bott, M. H. P. Overseas Geol. & Min. Resources, 8, 260-278). Holotype from

approximate depth of 110 feet; lat. 8°24' N, long. 13°06' W.

Derivation of name: Figured specimens: In honour of J. D. Pollet, for his geological investigations in Sierra Leone.

British Museum (Nat. Hist.) nos. **OS12288** (holotype, \$\Pi\$ RV, \$\SLBH9-9\$: Pl. **11**, 78, fig. 1), **OS12287** (\$\Pi\$ LV, \$\SLBH9-12\$: Pl. **11**, 76, fig. 1), **OS12289** (\$\Sigma\$ RV, \$\SLBH9-9\$: Pl. **11**, 78, figs. 2, 3),

destroyed (& LV, SLBH9-9: Pl. 11, 76, fig.2), OS12290 (\$\hat{P}\$ RV, SLBH9-9: Pl. 11, 80, figs. 1, 2, 3, 4, Pl. 11, 82, fig. 1), OS12291 (\$\Pi\$ RV, \$LBH9-10: Pl. 11, 82, figs. 2, 3), OS12292 (\$\Pi\$ LV, \$LBH9-10: Pl. 11, 82, fig. 4). All specimens are from the type locality; depths of samples in borehole as

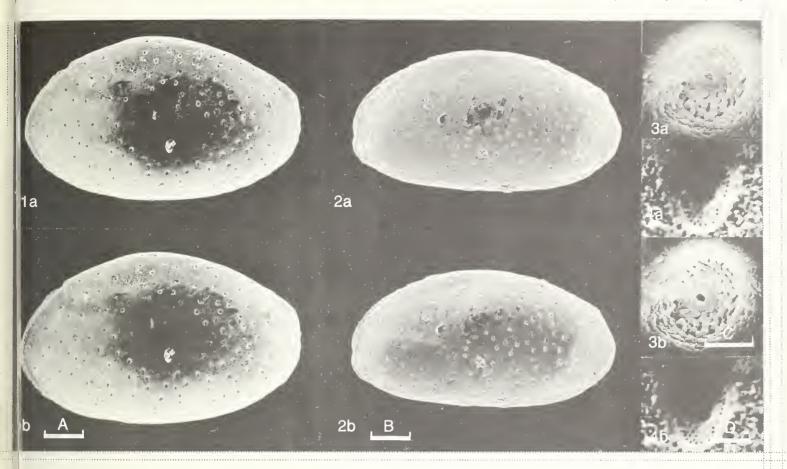

follows: SLBH9-9, 110 feet; SLBH9-10, 120 feet; SLBH9-12. 132-137 feet.

Because this is the only species known so far, see generic diagnosis.

Stereo-Atlas of Ostracod Shells 11, 81

Leocytheridea polleti (7 of 8)

Remarks:

There is variation in lateral outline, some specimens having a more arched dorsal margin than others (cf. Pl. 11, 76, fig. 2 and Pl. 11, 82, fig. 4; and Pl. 11, 78, fig. 1 and Pl. 11, 82, fig. 1); it seems unlikely that this character will be useful in species discrimination.

A slight hinge-ear tends to develop at the postero-dorsal angle of the left valve. The prominent normal pore canal openings give the surface a punctate appearance. The normal pore canals are sieve-type with a large central opening; the sieve plate is delicate and easily destroyed, leaving a pit with a large central opening at the base. There are about 100 normal pore canals.

The hinge is basically antimerodont; the right valve anterior tooth consists of five crenulations which become larger towards the anterior, the most anterior being quite large, bilobed, and almost like a small tooth in its own right; the situation is similar posteriorly, with four crenulations, the most posterior being larger. In the right valve the median element is a very shallow crenulate groove. Hinge of left valve is complementary.

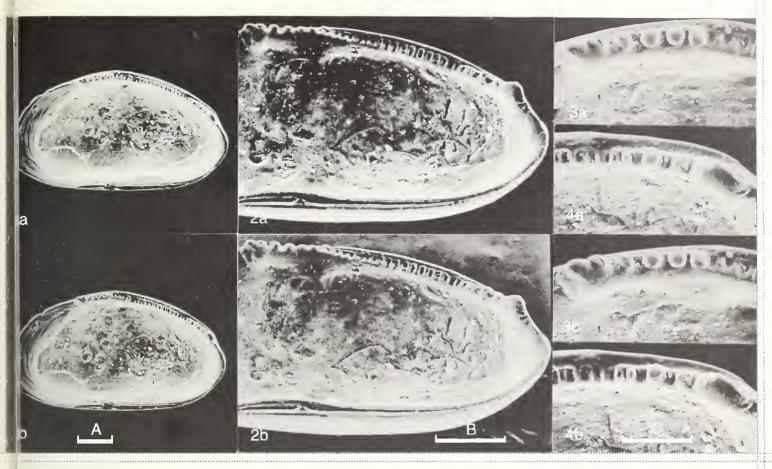

The line of the inner margin is irregular. There is a prominent indentation in the anteroventral angle, with the production of a small vestibule. There are some 34 anterior radial pore canals, arranged in three groups: the dorsal group of 14 are long, sinuous, often crossing each other, with many false canals; the second group is developed around the antero-ventral indentation, where there are some 15 short, straight, canals; the third group is found along the ventral part of the antero-ventral indentation where the canals are long and sinuous. There are some eight ventral radial pore canals and eight posterior radial pore canals.

The central muscle scars consist of a vertical row of 4 scars with a single frontal scar; the latter is approximately oval with a tendency to become 'U'-shaped or even almost to split into two. Mandibular scars are present, the most ventral of which lies in an indentation of the ventral inner margin.

Distribution: Known only from the type locality.

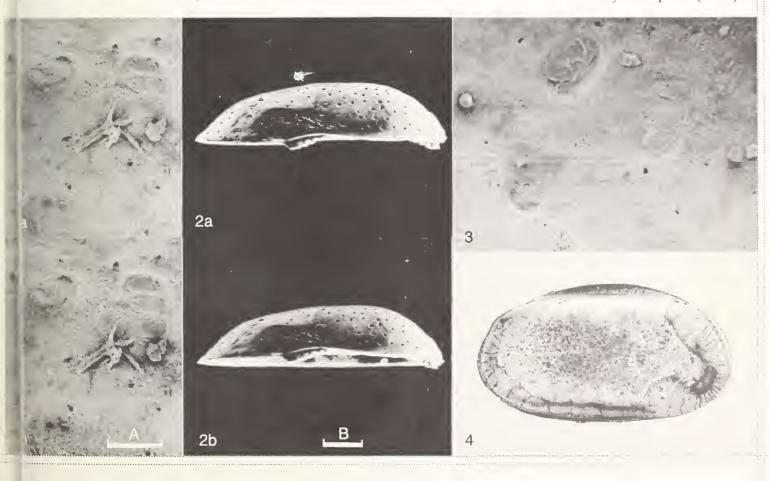

Explanation of Plate 11, 82

Leocytherida polleti (8 of 8)

ON ARCHEOCOSTA ALKAZWINII AL-BASHIR & KEEN

by J. M. T. Al-Bashir & M. C. Keen (University of Glasgow, Scoiland)

Genus ARCHEOCOSTA gen. nov.

Type-species: Archeocosta alkazwinii sp. nov.

Derivation of name: Greek arche, beginning; referring to the first or earliest of the Costa group.

Diagnosis: Trachyleberidinae with four longitudinal ridges, ventral ridge often indistinct on left valve; no sub-

central tubercle; reticulate ornamentation; carapace subrectangular in lateral view with prominent anterior hinge ear in left valve, and pointed posterior end; males larger and more elongate than

females; hinge amphidont/heterodont.

Remarks:

Archeocosta is thought to belong to a group of costate ostracods which characterised the late Cretaceous and Palaeogene shallow marine waters of the southern shores of Tethys. Paracosta Siddiqui, 1971 and Paleocosta Benson, 1977 are other members of the group which are found in West and North Africa, the Middle East, and Pakistan. Archeocosta (Cenomanian-Santonian) is considerably older than Paracosta and Paleocosta (Maastrichtian-Oligocene) and may be ancestral to them. These ostracods have a dorsal ridge, two median ridges, and a marginal ventral ridge; Paracosta and Paleocosta frequently develop a short fifth ridge between the two median ridges, a feature not seen in Archeocosta. It needs to be emphasised that the ventral ridge is very close to the ventral margin, but it is this ridge that is continuous with the anterior and posterior marginal rims; the lower median ridge might be confused with the normal position of the ventral ridge, and it is not continuous with the marginal rims. Paracosta and Paleocosta differ from each other principally in the strength of ornamentation, Paleocosta having more prominent longitudinal ridges with coarser and

Explanation of Plate 11, 84

Fig. 1, \Im car., ext. rt. lat. (OS 12293, 540 μ m long); fig. 2, \Im car., ext. rt. lat. (holotype, OS 12294, 630 μ m long); fig. 3, \Im car., ext. rt. lat. (OS 12295, 620 μ m long); fig. 4, \Im car., ext. rt. lat. (OS 12299, 720 μ m long). Scale A (100 μ m; × 94), fig. 1; scale B (100 μ m; × 82), figs. 2, 3; scale C (100 μ m; × 69), fig. 4.

Stereo-Atlas of Ostracod Shells 11, 85

Archeocosta alkazwinii (3 of 8)

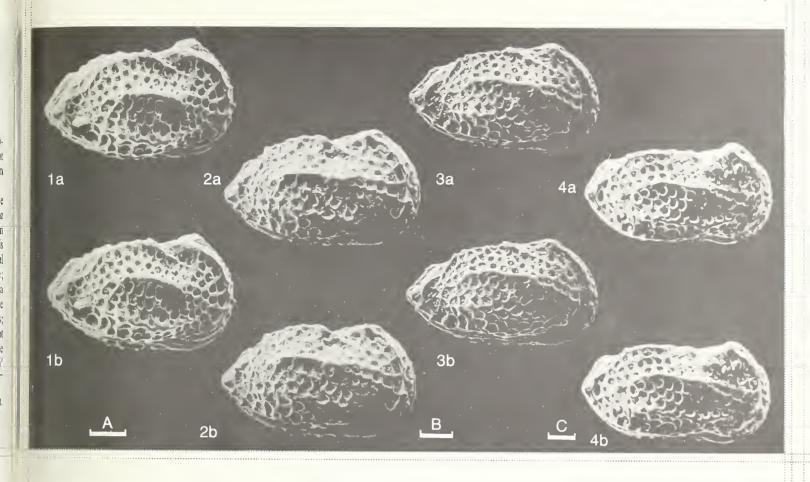

Remarks (contd.):

more regular intercostal reticulation. Al-Sheikhly ('Maastrichtian-Upper Eocene Ostracoda of the subfamily Trachyleberidinae from Iraq, Jordan and Syria'; unpublished Ph.D. thesis, Univ. of Glasgow 1980) considered such differences to warrant subgeneric distinction only.

Archeocosta is similar to these two taxa in many details, including the presence of a short eyerib, two small ridges bifurcating from the posterior end of the dorsal ridge, the distribution of pore cones, and internally the crescentic anterior tooth of the right valve. It differs in the asymmetry of the valves, whereby the ventral ridge is always distinct in the right valve but not always easily seen in the left; in having a shorter and less prominent ridge running from the eye-tubercle towards the subcentral area; in frequently having two ridges running from the anterior end of the upper median ridge; and in the absence of any clear bifurcation at the posterior end of the upper median ridge. Internally Archeocosta differs in having a smooth hinge bar, unlike the crenulate bar of Paracosta and Paleocosta. There is a possibility that the smooth hinge bar of Archeocosta could be due to preservation because individual specimens of the two other genera may have smooth hinge bars on this account, and specimens which may be conspecific with A. alkazwinii have been described by Sayyab ('Cretaceous Ostracoda from the Arabian Gulf Area'; unpublished Ph.D. dissertation, State University of Iowa, 1956) with a crenulate hinge bar (see A. alkazwinii below). Most species of Paracosta and Paleocosta also have a narrow anterior vestibule, a feature not observed so far in Archeocosta, Cythereis Jones, 1849 differs in having only three longitudinal ridges, a prominent subcentral tubercle, and denticulate anterior and posterior hinge elements. Dumontina Derro, 1966 differs in outline, lacks a hinge-ear, has less prominent and a more irregular number of longitudinal ridges, and has denticulate or lobate anterior and posterior hinge elements. Trachyleberidea Bowen, 1953 differs in having a sharply pointed posterior end, only three longitudinal ridges, and lobate terminal hinge elements. Hazelina Moos, 1966 has only three longitudinal ridges which tend to be thicker, the median ridge curves upwards at the posterior to join the dorsal ridge, has a subcentral tubercle, and has lobate terminal hinge elements. Costa Neviani, 1928 differs in the presence of only three longitudinal ridges and the frequent discontinuity of the antero - marginal rim.

Archeocosta alkazwinii (4 of 8)

Archeocosta alkazwinii sp. nov.

Holotype: British Museum (Nat. Hist.) no. OS12294; 9 carapace.

Type locality: South Rumaila Well-104, south eastern Iraq, lat. 30°05'E, long. 47°23'N; Khasib Formation,

Lower Coniacian, drilling depth of 2386 m.

Derivation of name: Figured specimens:

After Zakariyy Al-Kazwini, a famous thirteenth century Arab cosmologist and geographer. Brit. Mus. (Nat. Hist.) nos. **OS 12293** (\$\partial \cap \text{car.}, \depth 2386 \text{ m: Pl. 11}, 84, \text{fig. 1}; Pl. 11, 88, \text{fig. 5}), **OS 12294** (holotype, \$\partial \cap \text{car.}, \depth 2386 \text{ m: Pl. 11}, 84, \text{fig. 2}), **OS 12295** (\$\partial \cap \text{car.}, \depth 2414 \text{ m: Pl. 11}, 84, \text{fig. 2}), **OS 12305** (\$\partial \cap \text{car.}, \depth 2414 \text{ m: Pl. 11}, 84, \text{fig. 4}), **OS 12305** (\$\partial \cap \text{car.}, \depth 2400 \text{ m: Pl. 11}, 86, \text{fig. 3}), **OS 12296** (\$\partial \cap \text{car.}, \depth 2412 \text{ m: Pl. 11}, 86, \text{fig. 4}), **OS 12297** (\$\partial \cap \text{car.}, \depth 2416 \text{ m: Pl. 11}, 88, \text{fig. 1}), **OS 12301** (\$\partial \cap \text{car.}, \depth 2424 \text{ m: Pl. 11}, 88, \text{fig. 3}), **OS 12310** (\$\partial \cap \text{car.}, \depth 2386 \text{ m: Pl. 11}, 88, \text{fig. 6}), **OS 12307** (\$\partial \cap \text{RV}, \depth 2416 \text{ m: Pl. 11}, 90, \text{fig. 3}), **OS 12308** (\$\partial \cap \text{LV}, \depth 2414 \text{ m: Pl. 11}, 90, \text{fig. 4}); all from the Khasib Formation of South Rumaila Well-104. Specimens **OS 12303** (\$\partial \cap \text{car.}, \depth 2342 \text{ m: Pl. 11}, 88, \text{fig. 2}), **OS 12306** (\$\partial \cap \text{car.}, \depth 2348 \text{ m: Pl. 11}, 90, \text{fig. 2}) are from the Tanuma

Khasib Formation of Kifl Well-2.

Diagnosis:

Because this is the only species so far known, see generic diagnosis.

Remarks:

The dorsal ridge bears some prominent pore cones which sometimes give it a sinuous appearance; it bifurcates at the posterior, the lower branch being a short curved ridge ending at the "terminus" pore cone. The upper median ridge is variable in length and prominence, and in most specimens thickening of the anterior reticulation muri form two thin ridges running from the anterior end of the upper median ridge towards the anterior margin. The reticulation between the two median ridges varies in strength between specimens. The marginal ventral ridge is only clearly seen on the right

Formation of South Rumaila Well-104. OS 12304 (& car., depth 4420 ft: Pl. 11, 86, fig. 2) is from the

Explanation of plate 11, 88

Fig. 1, $\$ car., ext. lt. lat. (OS 12297, 640 μ m long); fig. 2, $\$ car., ext. lt. lat. (OS 12300, 720 μ m long); fig. 3, $\$ car., ext. lt. lat. (OS 12301, 742 μ m long); fig. 4, $\$ car., ext. vent. (OS 12310, 630 μ m long); fig. 5, $\$ car., ext. dors. (OS 12293, 540 μ m long); fig. 6, $\$ car., ext. dors. (OS 12309, 630 μ m long). Scale A (200 μ m; \times 82), figs. 1, 5; scale B (200 μ m; \times 72), figs. 2–4, 6.

Stereo-Atlas of Ostracod Shells 11, 89

Archeocosta alkazwinii (7 of 8)

Remarks (contd.):

valve of both males and females; at the posterior it is continuous with the posterior marginal rim; at the anterior it converges towards the lower median ridge and in some specimens a branch of it is continuous with the anterior marginal rim. The reticulation varies in strength between specimens at both the anterior and posterior. There is no true sub-central tubercle, although some specimens show a slight prominence where the upper median ridge bifurcates at the anterior. Eye tubercle prominent. 6–10 anterior and 5–6 posterior denticles. Pore cores often prominent.

Internally, the marginal area is broad, there are no vestibules, the selvage is distinct. The hinge of the right valve has a crescentic-shaped smooth anterior tooth with a higher conical dorsal part and a lower ventral part extending below the postjacent socket, the latter being deep, smooth, and rounded; the median groove appears to be smooth; the posterior tooth is a large hemispherical boss; the hinge of the left valve is complementary. The muscle scars could not be observed.

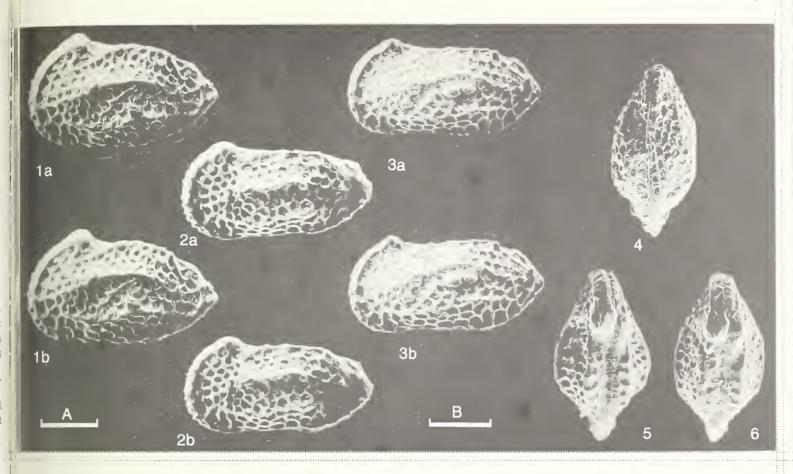

A. alkazwinii is probably synonymous with 'Mesocythereis reticulata' Sayyab M.S. (86–87, pl. 3, figs. 23, 24, text-fig. 20) from the Upper Cretaceous of the Arabian Gulk, although Sayyab describes a crenulate hinge bar and a reniform posterior tooth. Paracosta declivis Siddiqui, 1971, the type-species of the genus from the Upper Eocene of Pakistan differs in the absence of a hinge ear and the presence of a much longer upper median ridge. Paracosta arabica (Bassiouni, 1969) from the Palaeocene-Eocene of N. Africa and the Middle East differs in having a more bluntly rounded posterior margin, a weak hinge ear, and less prominent longitudinal ridges.

A alkazwinii shows considerable range in size, with females varying between $540\,\mu\text{m}$ and $640\,\mu\text{m}$ in length and males between $630\,\mu\text{m}$ and $750\,\mu\text{m}$. The size distribution is continuous, with no obvious groupings, and smaller and larger individuals may occur in the same sample (compare Pl. 11, 84 fig. 1, a small form $L = 540\,\mu\text{m}$, with the holotype, Pl. 11, 84, fig. 2, $L = 630\,\mu\text{m}$). The smaller individuals have the same ornamentation as the larger, are heavily calcified, and have a fully developed amphidont hinge. It is felt justified to regard them as adult and not a case of precocious sexual dimorphism, but it is impossible to determine whether the size variation is an environmental or genetic phenomenon.

Distribution: Turonian to Coniacian of Iraq.

Table 1. Measurements on specimens (N = no. of specimens; \overline{x} = mean; L = length; H = height; W = width); A = valves, B = carapaces.

Diagnosis:

In the lateral view valves subtriangular, anterior end broadly rounded, posterior end narrowly rounded ventrally. Both valves with small peripheral nodes along the anterior and posterior margins. Left valve considerably larger than right valve, overlapping it on all sides. Surface of the valves coarsely pitted; eye-tubercles distinct. In dorsal view carapaces subrhomboidal to elongate-fusiform.

Stereo-Atlas of Ostracod Shells 11, 97

Schuleridea oculata (7 of 8)

Remarks

Sexual dimorphism pronounced. Shell morphotype B more elongate, lower and in dorsal view narrower than morphotype A. As the genus *Schuleridea* is not yet represented by living species, it is supposed that the males are represented by Morphotype B.

The hinge is divided into three elements in each valve. The terminal elements are dentate plates (RV) or loculate sockets (LV); the median element is subdivided into three parts – proximal, central and distal. The proximal and distal parts are smooth; the proximal part, however, being much broader than the distal part. The central parts – a groove (RV) or a ridge (LV) – are furnished with fine striations, and form a part of the opening mechanism (discussed in detail by Weiss 1983).

Numerous, funnel-type normal pores open on elevated parts of the shell. Marginal porecanals are also very numerous (approx. 60 anteriorly). They reach the outer surface distally of the flange and their openings on the exterior surface of the shell form a zigzag line.

Distribution:

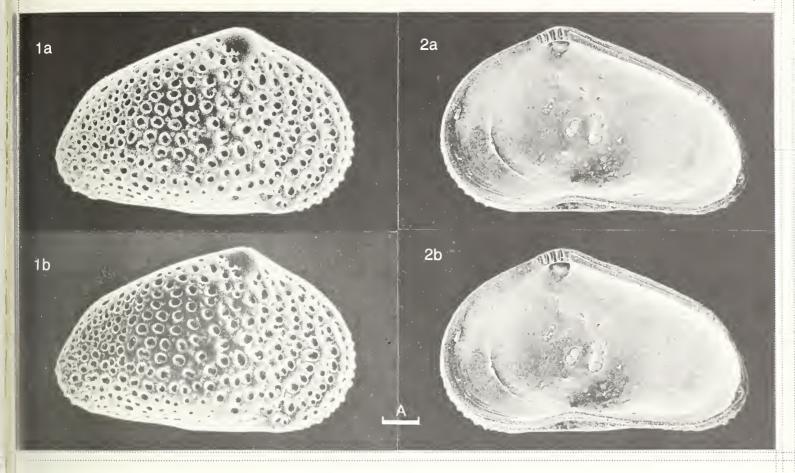

Line of concrescence and inner margin are very slightly separated along the anterior margin. Upper Oligocene: Astrup near Osnabrück, Germany (Lienenklaus 1894, Moos 1970, op. cit.); Doberg near Bünde, Germany (Lienenklaus 1894, Moos 1970, op. cit.); Shaft Kapellen (Lower Rhine Basin), Germany (Ellerman 1958, Moos 1970, op. cit.); Shaft Rossenray (Lower Rhine Basin), Germany (van den Bold 1963); Shaft Tönisberg (Lower Rhine Basin), Germany (Weiss 1983); Kassel, Germany (Moos 1970 op. cit.); Volpriehausen near Uslar (boring), Germany (Moos 1970, op. cit.); Höllkopf near Glimmerode (Basin of Kassel), Germany (Faupel 1975, op. cit.); Niedersachsen (borings), Germany (Uffenorde 1980, 1981, op. cit.).

Remarks:

Loxoconcha multiornata (3 of 4)

A small ($< 500 \,\mu \text{m}$ long) species of Loxoconcha with straight parallel dorsal and ventral margins. Diagnosis:

Surface ornamentation consists of coarse, deep reticulations with tendency toward development of irregular ribbing pattern. There is a well developed eye tubercle and strong sexual dimorphism.

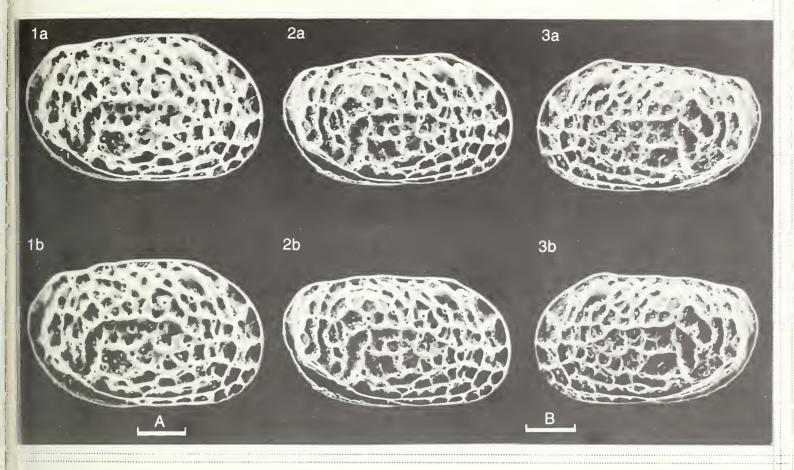

The external morphology of this species somewhat resembles L. kitanipponica Ishizaki, 1971, but differs in having a reticulate surface with irregular ribbing pattern. L. ornatovalvae Hartmann, 1964

very closely resembles L. multiornata but is differentiated by its less prominently developed dorsal

ridge. Furthermore, the two species differ in details of ornamentation, particularly in the ribbing

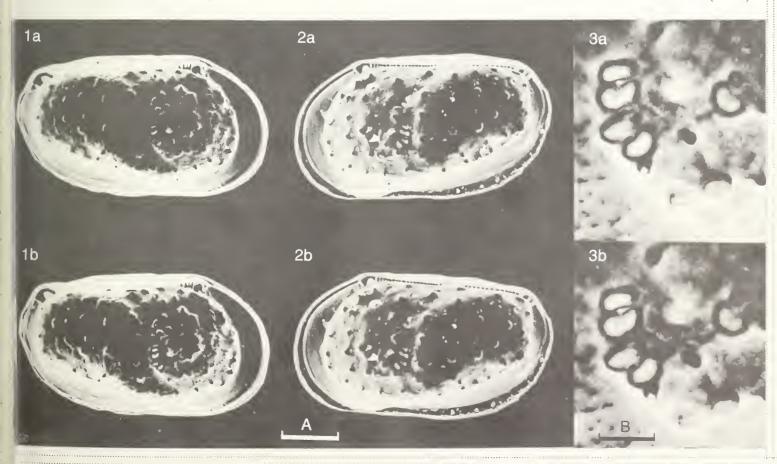

Distribution: L. multiornata has been found on the west coast of India (Jain, op. cit.) and in the Arabian Gulf

(Bate & Gurney, op cit., and herein).

Stereo-Atlas of Ostracod Shells 11, 102

Loxoconcha multiornata (4 of 4)

ON LOXOCONCHA UNDULATA AL-FURAIH sp. nov.

by Ali A. F. Al-Furaih (King Saud University, Riyadh, Saudi Arabia)

Loxoconcha undulata sp. nov.

1971 Loxoconcha sp. C.; R. H. Bate, Bull. Centre Rech. Pau SNPA, suppl. 5, 246, 250, pl. 3, figs. 2n, 3n.

1981 Loxoconcha (Loxoconcha) indica Jain; R. H. Bate & A. Gurney, Bull. Br. Mus. nat. Hist. (Zool.), 45(5), 240, 241, figs. 5A-H; non Loxoconcha megapora indica Jain, 1978.

Holotype: King Saud University coll. KSU.G.OS. 210; ♀ RV.

Type locality: Jazirat Tarūt coast, Arabian Gulf (approx. lat. 26° 35'N, long. 50° 05'E); Recent, marine.

Derivation of name: Latin undulatus, wavy; referring to the fancied resemblance of the anterior and posterior ornamen-

tation to a wavy sea.

Figured specimens: King Saud University coll. nos. KSU.G.OS. 210 (holotype, \$2 RV: Pl. 11, 104, fig. 1), KSU.G.OS.

211 (ở LV: Pl. 11, 104, figs. 2, 3), KSU.G.OS. 212 (♀ LV: Pl. 11, 106, fig. 1), KSU.G.OS. 213 (♂

RV: Pl. 11, 106, figs. 2, 3). All the figured specimens are from the type locality.

Explanation of Plate 11, 104

Fig. 1, \mathcal{P} RV, ext. lat. (holotype, KSU.G.OS. 210, 445 μ m long); figs. 2, 3, \mathcal{E} LV (KSU.G.OS. 211, 470 μ m long): fig. 2, ext. lat.; fig. 3, ext. lat., detail showing sieve-plate.

Scale A ($100 \mu m$; ×150), fig. 1; scale B ($100 \mu m$; ×140), fig. 2; scale C ($10 \mu m$; ×1900), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 105

Loxoconcha undulata (3 of 4)

Diagnosis: Carapace subrhomboidal in lateral view. Dorsal margin very slightly concave just posterior to the middle. Ventral margin sinuous, concave anterior to the middle. Shell surface punctate with scat-

tered rounded sieve pores. Eye spot low but distinct.

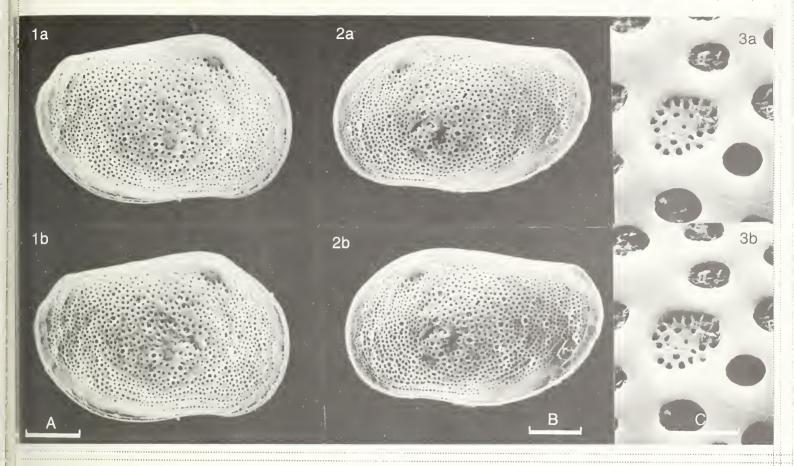

Remarks: This species was first recorded in the Arabian Gulf by Bate (1971) and described and illustrated by

Bate & Gurney (1981), but they considered it conspecific with Loxoconcha megapora indica Jain, 1978, from the west coast of India. L. indica differs in having a straight dorsal margin, less distinct posterior cardinal angle and a much more finely punctated surface. Furthermore, L. undulata has a more broadly convex postero-ventral margin and the eye tubercle is situated in a lower position. The present species is somewhat similar to L. matagordensis Swain, 1955, from San Antonio Bay, Texas coast, but differs in having a more distinct posterior cardinal angle. L. pseudovelata Stancheva, 1964, from the Upper Miocene of Bulgaria is very closely related species but differs in details of outline

and having reticulate surface.

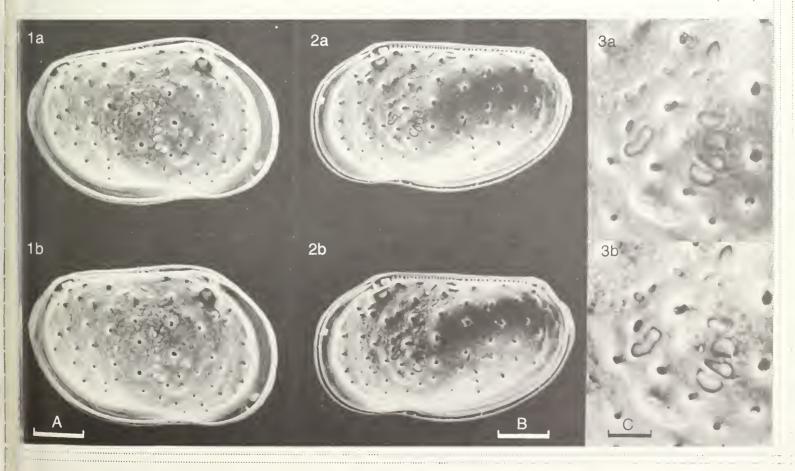

Distribution: L. undulata has been found at several localities in the Arabian Gulf (Bate & Gurney, op. cit., and

herein).

Stereo-Atlas of Ostracod Shells 11, 109

Loxoconcha amygdalanux (3 of 4)

Diagnosis: Loxoconcha species with elongate carapace and distinct posteroventral depression. Shell surface

reticulate with concentrically arranged fossae. Fossae are coarser in the middle portion of the cara-

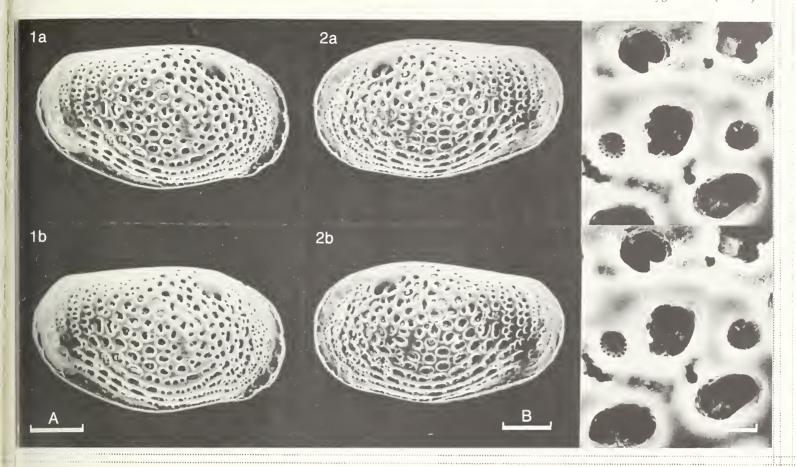

pace, finer towards anterior and posterodorsal.

Remarks: This species is unlikely to be confused with other described species of the genus. It has a distinct out-

line and coarse ornamentation, particularly in the centre of the carapace.

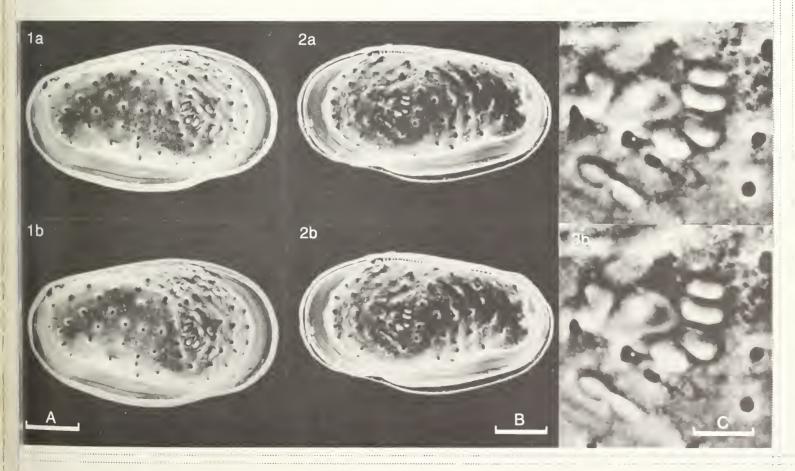

Distribution: This species has so far only been found in the Arabian Gulf (Bate & Gurney, op. cit. and herein) and

the Gulf of Oman (Paik, op. cit.).

Loxoconcha amygdalanux (4 of 4)

ON RAIMBAUTINA HAMMANNI VANNIER gen. et sp. nov.

by Jean Vannier (University of Rennes, France)

Genus RAIMBAUTINA gen. nov.

Type-species: Raimbautina hammanni sp. nov.

Derivation of name:

In honour of Raimbaut de Vaqueiras (1155-1207), french troubadour. Gender feminine.

Diagnosis:

Median-sized palaeocope; adults 1-1.3 mm long (without the posteroventral spine). Two lobal areas (L3 + L4 & L1 + L2) occur either side the main sulcus (S2) which is slightly sigmoidal. L3 is oblique to the dorsal margin and has a well-marked swelling in its ventral part. Anterior lobal area (L1 + L2)with a distinct preadductorial node (L2). Posterior lobe (L4) is a low swelling and poorly defined. Velum represented anteriorly by a curved, shield-like flange extended into a spine, joined to the lobal area (ventral part of L2) by a connecting strut. Long spine, itself spinose, occurs posteroventrally and projects posteriorly. Laterovelar furrow well developed.

Remarks:

Raimbautina gen. nov. differs from all other known genera by its very distinctive posteroventral spine and its shield-like velvar flange tapering towards the posterior and connected to the anterior lobal area.

Raimbautina shows some morphological similarities in its velum, lobes and sulci with certain genera belonging to the Family Ctenonotellidea Schmidt, 1941. Bilobatia (cf. Schallreuter, Stereo-Atlas of Ostracod Shells, 9, 1982), Rakverella (cf. Schallreuter, Palaeontographica A, 153, 1976) and Schallreuteria (cf. Siveter, Stereo-Atlas of Ostracod Shells, 9, 1982) have a velar sculpture (female valves) comparable to that of *Raimbautina*. As far as lobal and sulcal morphology is con-

Explanation of Plate 11, 112

Figs. 1-3, LV (holotype, IGR 5700/A2, 1255 μm long): fig. 1, ext. lat.; fig. 2, ext. dors. obl., fig. 3, ext. vent. obl. Scale A (250 μ m; × 70), figs. 1-3.

Stereo-Atlas of Ostracod Shells 11, 113

Raimbautina hammanni (3 of 8)

Remarks (contd.): cerned, Raimbautina displays both wehrline and ctenonotelline characteristics: lobe L3 is strongly developed and lobe L4 is poorly defined.

At present Raimbautina is monotypic and any possible dimorphism of the genus is unknown.

Rainibautina hamnianni sp. nov.

Institut de Géologie, University of Rennes (IGR), coll. no. 5700/A2, LV.

[Paratypes: IGR coll. nos. 5700/B1, LV; 5701/A, RV; 5710/A1, LV; 30270/4, RV; 30336/1,

Type locality:

Siltstones and mudstones on the path leading to the farm of l'Aubaudais, Guichen, Ille-et-Vilaine,

France; lat. 47° 58′ 8′′ N, long. 1° 44′ W. Traveusot Formation, Llandeilo Series, Ordovician.

Derivation of name:

In honour of Dr. W. Hammann, University of Würzburg, West Germany.

Figured specimens:

Institut de Géologie, University of Rennes (IGR), coll. nos. 5700/A2 (holotype, RV: Pl. 11, 112, figs. 1-3; Pl. 11, 114, figs. 1, 2), 5701/A (RV: Pl. 11, 114, figs. 3-5), and 5700/B1 (LV: Pl. 11, 116,

figs. 1-3; Pl. 11, 118, figs. 1, 2). All specimens are from the type-locality. All the figured specimens

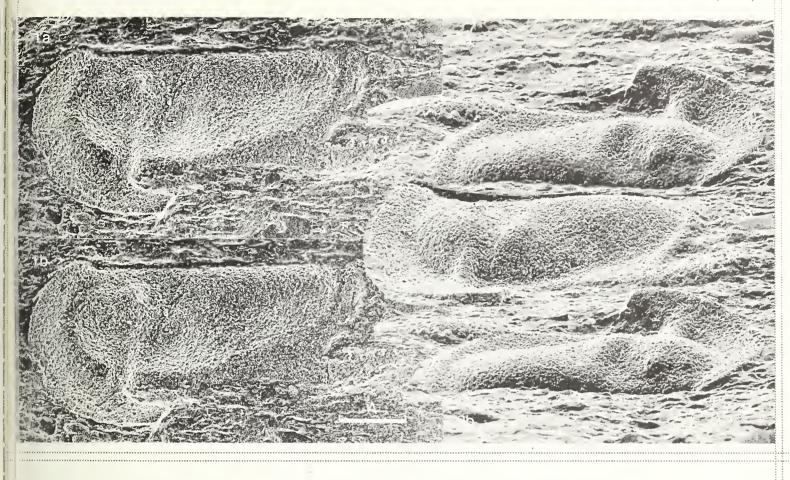

are latex casts taken from external moulds.

Diagnosis:

As for the genus.

Stereo-Atlas of Ostracod Shells 11, 114

Raimbautina hammanni (4 of 8)

Remarks:

Distribution:

From a structural point of view, the posteroventral spine and the frontal velar flange of *Raimbautina hammanni* are surely not merely simple ornamental features. The function of such velar projecting structures can be interpreted in a number of possible ways (Text-figs. 1a-c):

1. The two enormously long spines on the posteroventral part of each valve may have served as posterior supporting points when the animal was resting on the substrate with the carapace closed (Text-Fig. 1b). Added to the contact points of the frontal velar flanges, they would act as stabilizing structures. The frontal velar flanges extend both ventrally and laterally outward and the two posterior spines are projected and divergent towards the posterior. The supporting plane would be wider when the carapace was slightly open, as in a feeding or active attitude. The fact that a strong connection occurs between the velar flange and L2 supports this hypothesis. Such a strengthening structure lies just above a possible contact point with the substrate. This interpretation is consistent with a benthic mode of life.

2. The posteroventral spines (projected backwards, provided with secondary spines) suggest a defensive function whether the animal was resting on the sea-floor in contact with its frontal

flanges, or was crawling on the substratum, or was swimming (Text-figs. 1a, c).

3. The posteroventral spines of *Raimbautina hammanni* are not hollow projections (in contrast to the dorsal spines of genera such as *Aechmina*) and cannot be considered as buoyancy organs. Nevertheless, their position might suggest that they served as lateral stabilizing structures during swimming. Despite its unhydrodynamically-shaped carapace, an occasional swimming mode of locomotion near the bottom may have been aided by such projecting structures (Text-fig. 1c). In the Armorican Massif, France, *Raimbautina hammanni* occurs in several localities south of Rennes (Martigné-Ferchaud synclinorium) near the type locality at Guichen, Ille-et-Vilaine. It is also known from one locality in Normandy (Ger, Manche) and from one locality in the Laval synclinorium at Andouillé, Mayenne.

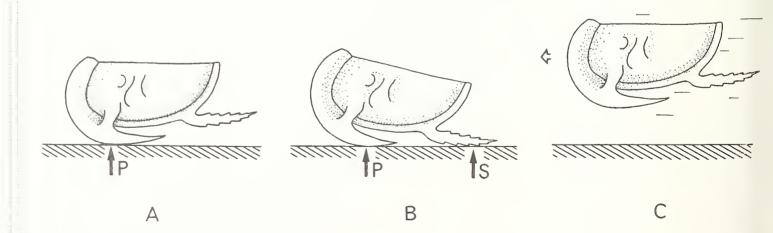

R. hammanni has also been obtained from the Iberian peninsula: from the eastern part of the Sierra Morena, central Spain, near Corral de Calatrava (Ciudad Real district), and from the Toledo Mountains at a locality between Puerto Rey and Puerto de San Vicente. All middle Ordovician.

Explanation of Plate 11, 116

Figs. 1-3, LV (paratype, IGR 5700/B1, 1185 μ m long): fig. 1, int. lat.; fig. 2, int. ant. obl.; fig. 3, int. post. obl. Scale A (250 μ m; \times 90), figs. 1-3.

Raimbautina hammanni (7 of 8)

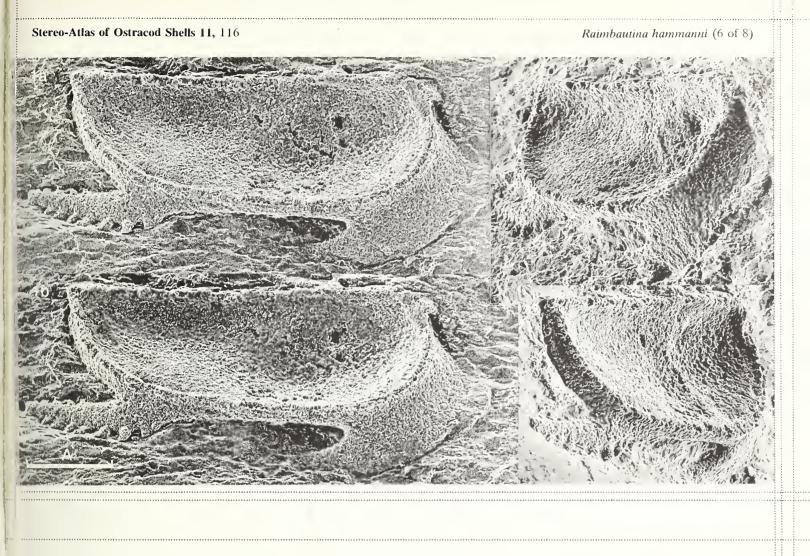

Text-fig. 1. Raimbautina hammanni gen. et sp. nov. Three possible life attitudes.

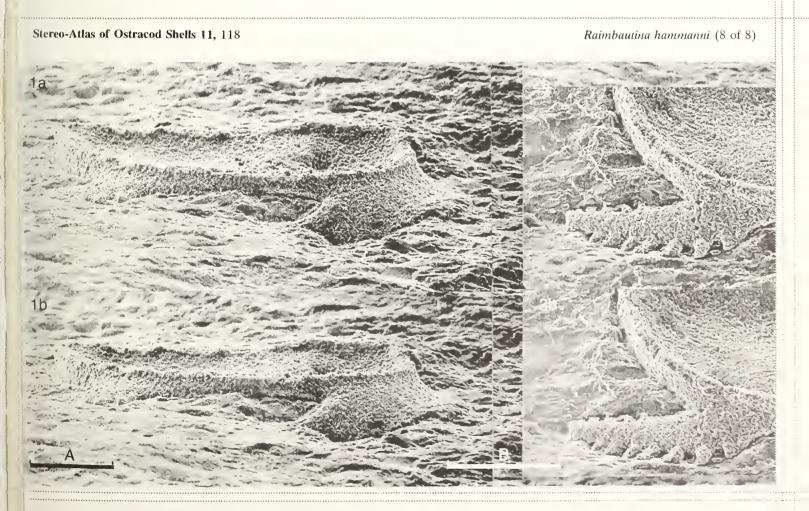

A-B: the ostracod is resting on the substrate (P = anterior supporting points; S = posterior supporting points). Position A suggests an active attitude, in contrast to position B.

C: the animal is swimming near the substrate.

Explanation of Plate 11, 118

Figs. 1, 2, LV (paratype, IGR 5700/B1): fig. 1, int. vent. obl.; fig. 2, vent. obl., detail showing postero-ventral spine. Scale A (250 μ m; × 90), fig. 1; scale B (250 μ m; × 120), fig. 2.

ON THIBAUTINA ROREI VANNIER gen. et sp. nov.

by Jean Vannier (University of Rennes, France)

Genus THIBAUTINA gen. nov.

Type-species: Thibautina rorei sp. nov.

Derivation of name:

Diagnosis:

In honour of Thibaut de Navarre (1201–1253), poet, trouvère, King of Navarre. Gender feminine. Small (length<0.8 mm) smooth binodicope; amplete. Short dorsal margin (length<0.75 mm); hypocline dorsum. Figure-of-eight-shaped ridge, rounded in tranverse section and 'open' dorsally, on valve lateral surface; in the medio-ventral part of the valve this ridge forms a bulb-like elevation. Sulcus S2 perpendicular to dorsal margin, wide, short and deep. In the central part of the valve, this sulcus is symmetrically extended into two narrow divergent depressions, giving an inverted-Y form. Marginal surface undifferentiated, convex or flat anterodorsally and posterodorsally.

Remarks:

Thibautina gen. nov. is comparable to several Ordovician genera such as Pedomphalella Swain & Cornell in Swain 1961, Kinnekullea Henningsmoen, 1948, Jonesites Coryell, 1930 and Cincinnaticoncha Warshauer, 1981, all belonging to the Superfamily Aechminacea Bouček, 1936. These genera have some important features in common with *Thibautina*: small-sized valves, length rarely exceeding 1 mm; and an arched ridge, rounded in section, more or less developed on the valve lateral surface. Nevertheless, Thibautina is distinguished from other genera by its crescent-shape ridge and its inverted-Y depression in the dorsal half of the valve. In many species of *Pedomphalella*, such as Pedomphalella egregia from the Caradocian of Baltoscandia (cf. Schallreuter, Ber. deutsch. Ges. geol. Wiss, A. Geol. Paläont. 13, pl. 2, fig. 2, 1968), the peripheral ridge overhangs a wide circular depression on the valve lateral surface, in contrast to that of *Thibautina rorei*.

Explanation of Plate 11, 120

Figs. 1–5, RV (holotype, IGR 5183/A1, 640 μm long): fig. 1, ext. lat.; fig. 2, ext. vent. obl.; fig. 3, ext. dors.; fig. 4, ext. post. obl.; fig. 5, ext. ant. obl.

Scale A (250 μ m; × 100), figs. 1–5.

Stereo-Atlas of Ostracod Shells 11, 121

Thibautina rorei (3 of 4)

Remarks (contd.):

Species of Jonesites such as Jonesites obliquus from the upper Ordovician of the USSR (cf. Neckaja, Trudy vses neft. naučhno-issed, geol. -razv. Inst., 20, 251, pl. 3, fig. 11, 1966), and species of Kinnekullea such as Kinnekullea thorslundi from the uppermost Caradocian of Sweden (cf. Henningsmoen, Bull. geol. Instn Univ. Upsala, 32, 414, pl. 27, figs. 7-9, 1948), have an incomplete ridge parallel to the free margin and in many cases it is connected with node(s) near the dorsal margin. In the American Cincinnaticoncha (cf. type-species C. pedigera Warshauer, J. Paleont., 55, pl. 1. figs. 13-19, 1981) the ridge is prominent and arched dorsally (as in *Thibautina rorei*), but is developed as an horizontally-disposed J-shaped lobe in contrast to that of the Armorican species. Two species belonging to the genus Rivillina Vannier, 1983, from the Ordovician of France (Armorican Massif) and Spain (cf. Vannier, Alcheringa, 7, 1983), also exhibit a ridge of a similar type to that of *Thibautina rorei*, but the shape and extent of the ridge differs between the two genera.

Thibautina rorei sp. nov.

Holotype:

Institut de Géologie, University of Rennes (IGR), coll. no. 5183/A1; RV.

[Paratypes: IGR coll. nos. 5181/A12, RV; 5184/B1, RV; 5184/C, RV; 5180/A, RV].

Type locality:

Bed with phosphatic pebbles within the siltstones and mudstones of the Domfront section (samples DF-9), Orne, France (cf. F. Paris, Mém. Soc. géol. minéral. Bretagne, 26, 1981); lat. 48°36'24"N,

long. 0°41′6″ W. Lower part of the Pissot Formation, Llanvirn Series, Ordovician.

Derivation of name: Figured specimens: In honour of Cipriano de Rore (1516-1565), Italian musician of the Renaissance.

Institute de Géologie, University of Rennes (IGR) coll. nos. 5183/A1 (holotype, RV: Pl. 11, 120, figs. 1–5) and $5184/\mathbb{C}$ (RV: Pl. 11, 122, figs. 1–3). Both from type locality; latex cats.

Diagnosis:

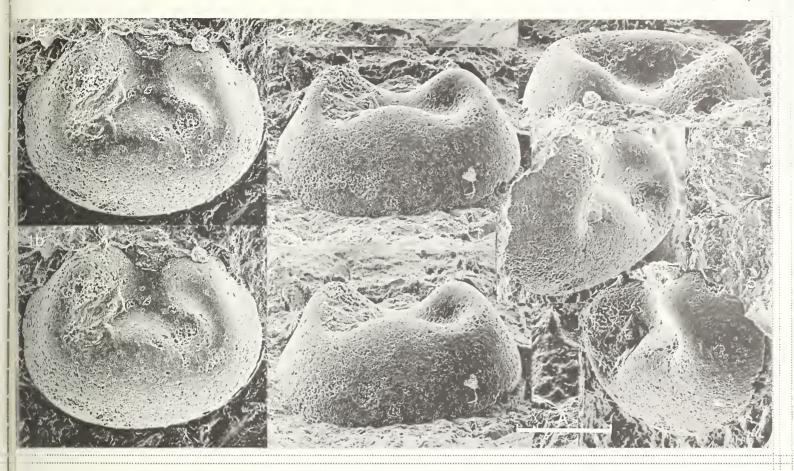

As for the genus. Monotypic.

Distribution:

At present, known only from the siltstones and mudstones of the type locality.

Derivation of name: Rune, old Nordic – germanic letter; alluding to the scars in the muscle spot.

Figured specimens: NM nos. 22740 (holotype, \$\Perp\$ LV: Pl. 11, 124, figs. 1, 2), 22741 (steinkern of paratype, juv. tecno-

morphic RV: Pl. 11, 126, figs. 1, 2) and 22742 (valve of paratype in the counterpart of rock: Pl. 11,

124, fig. 3; Pl. 11, 126, fig. 3). All from the type locality.

Diagnosis: Species of Platybolbina with a medium-sized muscle spot in a sulcal depression which continues

dorsally in an anterodorsal direction. Dolon weakly convex. Reticulation pattern moderately coarse.

Females c. 2.24 mm long.

Explanation of Plate 11, 124

Figs. 1, 2, LV (holotype, NM 22740, 2.24 mm long): fig. 1, int. lat.; fig. 2, photographical 'cast' of fig. 1; fig. 3, juv. tecnomorphic RV, int. lat., ornament behind muscle spot, photographical 'cast' (paratype, NM 22742, 1.66 mm long). Scale A (250 μm; × 37.5), figs. 1, 2; scale B (100 μm; × 90), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 125

Platybolbina runica (3 of 4)

Remarks:

The only two known valves of *P. runica* show only the inside of the shell and the exact nature of the external morphology of the shell is unknown. *P. runica* is clearly a member of *Platybolbina* but a subgeneric assignment, to either *P.* (*Reticulobolbina*) or *P.* (*Rimabolbina*) (cf. Schallreuter, *Geologie* 18, 877, 1969) is not possible because it is not yet known whether its muscle spot possesses a fissum or not. *P. runica* is the largest known species of *Platybolbina*. The previous known largest reticulate species is *P.* (*Reticulobolbina*) temperata Sarv, the holotype of which, a female valve, is 1.70 mm long (Sarv, *Eesti NSV Tead. Akad. geol. Inst. Uurim.*, 1, 39, 1956). The largest known species of *P.* (*Rimabolbina*), a subgenus known only from middle Ordovician, is *P.* (*R.*) omphalota Kesling (1.88 mm long; see Kesling, *Contr. Mus. Paleont. Univ. Mich.*, 15, 368, 1960). Contrarary to *P. runica*, both *P. omphalota* and *P. temperata* have very fine reticulation (Kesling, op. cit., pl. 8, figs. 4-6; Sarv, *Eesti NSV Tead. Akad. geol. Inst. Uurim.*, 4, pl. 2, figs. 2-3; Schallreuter, *Palaeontographica* (A), 180, pl. 27(13), fig. 6, 1983).

The muscle spot in the paratype (Pl. 11, 126, figs. 1-3) shows tiny impressions which could possibly represent individual attachment points of the adductor muscle scar. They appear to be arranged with one long oblique scar above several smaller attachment points, an arrangement which differs from that of *P.* (*Reticulobolbina*) integra (Schallreuter, op. cit., 878) which has a complex of many small scars. The small pit-like impression in front of the dorsal end of the muscle spot (see Pl. 11, 126, figs. 1-3) may represent an accessory muscle scar. It has a comparable position to the frontal

group of muscle scars of other ostracodes.

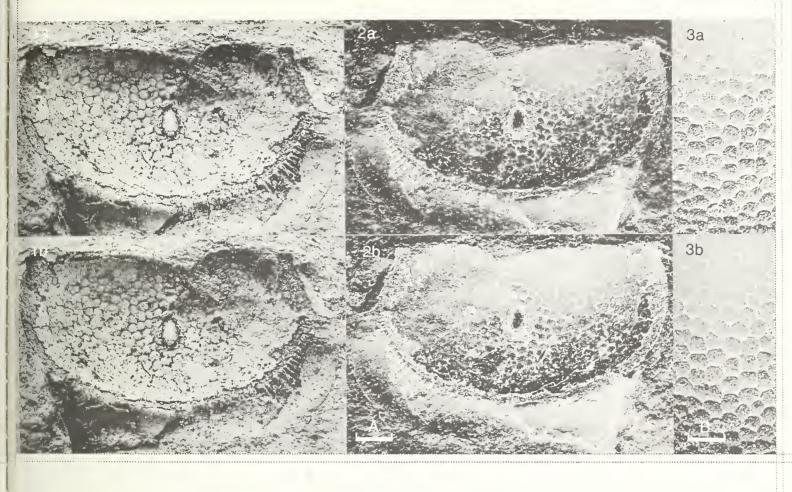

Distribution: Known only from type locality; upper Ordovician.

Explanation of Plate 11, 126

Figs. 1-3, juv. tecnomorphic RV (paratype NM 22741-2): figs. 1, 2, steinkern showing domicilium and anteroventral part of velum (NM 22741): fig. 1, ext. lat.; fig. 2, muscle spot; fig. 3, photographical 'cast' of the counterpart in rock (NM 22742), int. lat. Scale A (250 µm; × 49), figs. 1, 3; scale B (100 µm; × 95), fig. 2.

Platybolbina runica (4 of 4)

ON PIRETOPSIS (CERNINELLA) BOHEMICA (BARRANDE)

by R. E. L. Schallreuter, David J. Siveter & M. Kruta

(University of Hamburg, West Germany, University of Leicester, England & Academy of Sciences, Prague, Czechoslovakia)

Genus PIRETOPSIS Henningsmoen, 1953

1953 Piretopsis gen. n.; G. Henningsmoen, Norsk Geol. Tidsskr., 32, 43.

Protallinnella nov.; V. Jaanusson, Bull. geol. Instn Univ. Uppsala, 37, 353. 1957

Type-species (by original designation): Piretopsis donsi Henningsmoen, 1953

Subgenus CERNINELLA Přibyl, 1966

Cerninella gen. n.; A. Přibyl, Časopis národního muzea, odd. přírod., 135, 201. 1966

Type-species (by original designation): Beyrichia bohemica Barrande, 1872

Diagnosis:

See 'species diagnosis'. The subgenus is considered monotypic. Remarks:

Přibyl (1966) designated Beyrichia bohemica as the type-species of Cerninella. From the genera he compared with Cerninella, the baltoscandian Protallinnella Jaanusson is the most similar. However, this applies more to those Protallinnella species described by Sarv (Eesti NSV Tead. Akad. Geol. Inst. Uurim. 13, 166–171, 1963) than to the type-species P. grewingki (Bock, 1867), which is the oldest representative of the genus and which differs from Cerninella notably by its vertical lobes/cristae and relatively narrow S3 (see Öpik, Publ. Geol. Inst. Univ. Tartu, 44, pl. 2, fig. 1a). In 'B'. bohemica (middle Ordovician, Bohemia), S3 is very broad and the anterior lobes/cristae are oblique to the dorsal border. The other, slightly younger (upper Volkhovian/lower and middle Kundan) species of

Explanation of Plate 11, 128

Fig. 1, $\Re N$, ext. lat. (GPIMH 2948b, 3.47 mm long, excluding spines); fig. 2, posteriorly incomplete tecnomorphic LV, ext. lat., covered anteroventrally by the \$\text{ RV of fig. 1 (GPIMH 2948a, 3.24mm long).} Scale A (500 μ m; × 26), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 129

Piretopsis bohemica (3 of 10)

Remarks (contd.): Protallinnella described by Sarv (op. cit.), and Tetradella salopiensis Harper, 1947 from the Caradoc of Shropshire, assigned to Cerninella by Přibyl (1966, 203), form a gradual morphological transition series between the type-species of Protallinnella and Cerninella (cf., for example, Sarv, op. cit., pl. 4, figs. 5 – 10 and Siveter, Geol. J. Spec. Issue 8, 51, pl. 2, figs. 2–4, 1978). Thus, it is considered not possible to separate Cerninella as a distinct genus. This would blur not only its assumed natural relationships but also its phylogenetic and palaeogeographic implications.

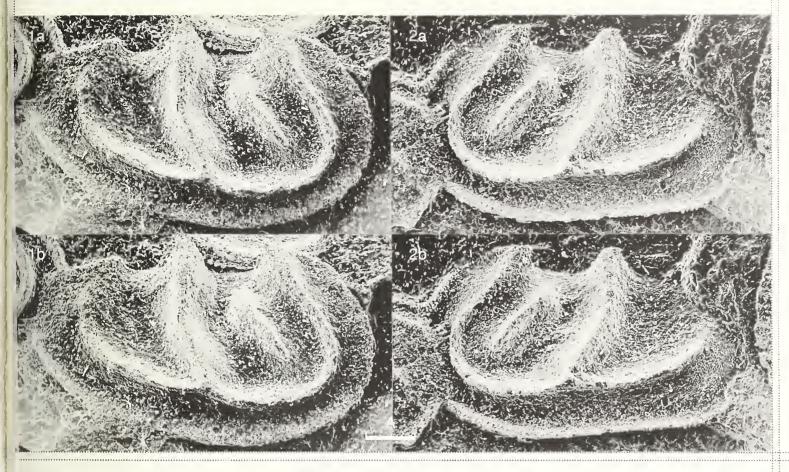

> Přibyl (1966, 202) assumed that Cerninella originated from Protallinnella (or related forms such as Tallinnellina). This seems to be correct. The stratigraphical occurrences and adult lengths of the relevant species agree with the morphological changes from oldest to youngest species: P. grewingki, Middle Volkhovian (1.30 mm); P. loennaensis, Upper Volkhovian (1.70 mm); P. salopiensis, Costonian (2.93 mm); P. bohemica, Vinice Stage (3.72 mm). P. bohemica appears, as expected, to be a morphologically advanced form. However, at the present state of knowledge it is hard to say whether it originates in a direct line from typical Protallinnella species or whether it forms a separate branch justifying a distinct subgenus. For the present Cerninella is retained at subgeneric level.

> The systematic position of the Bohemian material which Přibyl (1966) assigned to Cerninella complicata is also uncertain. The real Beyrichia complicata Salter, 1848, from the Llandeilo of Wales, has an anterior antrum like the type-species of *Tallinnella* and belongs to a new tallinnelline genus (Siveter, in press; cf., op. cit. 49, pl. 1, figs. 7, 8). The dimorphism of Přibyl's Bohemian material is unknown, but could possibly also belong to a tetradellid such as Ogmoopsis. If, however, the material does belong to Cerninella s.s. it would represent the oldest known species (Sarka Stage, upper lower or lower middle Ordovician) and would justify the subgeneric status of that taxon.

> A feature of Cerninella is the parable-like confluent C1 + C3, a pattern also present in the hitherto monotypic Piretopsis (middle Ordovician, 4aβ, of the Oslo Region), a genus which seems to be closely related to Protallinnella. Piretopsis differs from both Protallinnella and Cerninella by

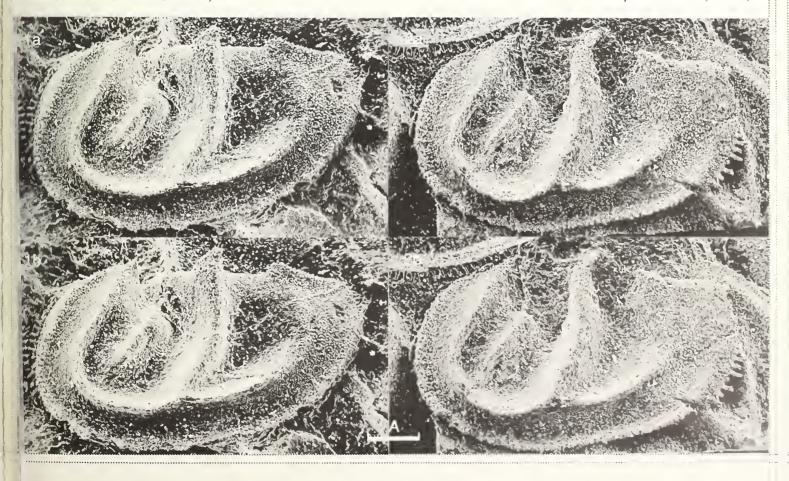

> > Explanation of Plate 11, 130

Fig. 1, tecnomorphic LV, ext. lat. (GPIMH 2949, 2.94mm long, excluding spines); fig. 2, tecnomorphic LV, ext. lat. (GPIMH 2950, 3.05 mm long, excluding spines). Scale A (500 μ m; ×28.5), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 130

Piretopsis bohemica (4 of 10)

Remarks (contd.): lacking C2, and also from Cerninella by its smaller S3. The "horn-like L1" of Piretopsis resembles the bulb-like L1 of internal moulds of Cerninella (Přibyl, op. cit., pl. 1(15), figs. 1, 2, 1966). Like Cerninella, Piretopsis is at present best considered a monotypic subgenus. Piretopsis was originally placed by Henningsmoen within the Piretellinae. Schallreuter (Geologie, 15, 200, 204, 1966) assigned Piretopsis to the Steusloffiinae and assumed an origin from Tallinnella. However, more probably, Piretopsis originates from Protallinnella in the lower Ordovician.

> The short, isolated C2 of P. (Cerninella) has an homeomorphic equivalent in Steusloffia, a genus which probably originated from Rigidella. In Rigidella, as in P. (Protallinnella), C2 is still connected with the other cristae (cf. Schallreuter, Palaeontographica A 153, text-fig. 6, 1976;

Jaanusson, op. cit., text-fig. 35D, 1957).

Distribution:

P. (Piretopsis): middle Ordovician (4ab) of Oslo Region. P. (Cerninella): see type-species. P. (Protallinnella): lower Ordovician (upper Oeland: B₂b-B₃b) of Baltoscandia, middle Ordovician (Costonian) of Welsh Borderland; also middle Ordovician (Llandeilo) of Morocco (J. Vannier, pers. comm.).

(GPIMH 2954, 2.96 mm long, excluding spines and dolon); fig. 3, tecnomorphic LV, ext. lat., ornament on posterior lobe (GPIMH 2949). Scale A (500 μ m; ×23), figs. 1, 2; scale B (100 μ m; ×110), fig. 3.

Stereo-Atlas of Ostracod Shells 11, 134

Piretopsis bohemica (8 of 10)

Lectotype:

National Museum, Prague; internal mould, \$\varphi\$ LV (not carapace as stated by Schmidt 1941). On a piece of almost black mudstone, no. L10010 [ex. CD 805, Inv. no. 1700]; figured by Müller & Zimmermann 1962, Müller 1963, 1978 and Přibyl in Spinar (loci cit.). Designated by E. A. Schmidt 1941, op. cit., 43; Barrande 1872, op. cit., pl. 34, figs. 19, 20; Přibyl 1966, op. cit., text-fig. 2a (drawing), pl. 1(15), fig. 1 (right hand side) [= Přibyl 1979, op. cit., text-fig. 3.2 and 11.1 (right hand side) respectively]. Barrande's drawing of the specimen chosen as lectotype does not agree in all details with the specimen considered as the lectotype by Přibyl but the latter is in all probability the type.

[Paratypes: 4 further pieces of rock, with many internal and external moulds, nos. L 10009 (part and counterpart), L 10011-L 10013. Pieces L 10009 and L 10011 are black mudstone; L 10012 and L 10013 consist of a mica- and limonite-rich dark-grey mudstone in which the ostracode shells are

replaced by limonite, and presumably come from another horizon].

Type locality: Figured specimens:

Vinice Formation, Caradoc. Trubín, near Králův Dvůr, Bohemia; lat. 49°3′ N, long. 14°2′ E. Geologisch-Paläontologisches Institut und Museum, University of Hamburg (GPIMH) nos. 2948a (tecnomorphic LV: Pl. 11, 128, fig. 2), 2948b (\$\Pi\$ RV: Pl. 11, 128, fig. 1; Pl. 11, 132, fig. 3), 2949 (tecnomorphic LV: Pl. 11, 130, fig. 1; Pl. 11, 134, fig. 3), 2950 (tecnomorphic LV: Pl. 11, 130, fig. 2), 2951 (tecnomorphic RV: Pl. 11, 132, fig. 1), 2952 (\$\times\$ RV: Pl. 11, 132, fig. 2), 2953 (\$\times\$ LV: Pl. 11, 134. fig. 1) and 2954 (\$\times RV: Pl. 11, 134, fig. 2). All GPIMH numbers refer to 'Silcoset' casts from the slab of black mudstone no. Ar 39170, Paleozoologiska sektionen, Naturhistoriska Riksmuseet, Stockholm; from the Vinice Formation, Caradoc Series of the type locality. The slab contains many external and a few internal moulds of P. (C.) bohemica, together with single valves of Hastatellina sp., Disulcinoides? sp. and Parapyxion? sp. Cast no. 2949 is probably of the same valve, on Ar 39169, as that figured by Jaanusson (1957).

Diagnosis:

Piretopsis (Cerninella) species with very broad S3 and bulb-like L1 and L3 at the dorsal border. C1 and C3 form a parable-like crista distinctly oblique (in anteroventral direction) to the dorsal margin, where each has a sharp cusp-like termination. C2 normally isolated from C1 + C3, dorsally extending to the mid-dorsal half of the valve. C4 connected with C1+C3 at a distinct angle, and absent dorsally except for a plica-like cusp at the dorsal margin. Velum is a rather narrow flange, sometimes undulate, from anterodorsal corner to gradual posterocentral termination. Velar dimorphism: dolon narrow, weakly convex; antrum very shallow. Marginal sculpture formed by a row of spines. Tiny spines along all parts of velar edge except dolon.

Stereo-Atlas of Ostracod Shells 11, 136

Piretopsis bohemica (10 of 10)

Remarks: P. (C.) bohemica is the youngest and largest (3.72 mm) Piretopsis species, differing from congeneric species mainly by its very broad S3, its oblique anterior lobes/cristae and its normally isolated C2. In the type-species, P. (Piretopsis) donsi (adult length 2.3 mm), C2 seems to be missing whereas in all P. (Protallinnella) species C2 is still connected with C1 + C3 and more or less perpendicular to the dorsal margin. In P. (Protallinnella) salopiensis (Harper, 1947) the anterior cristae are already slightly oblique to the dorsal margin. Furthermore, C4 in P. (P.) donsi is separated from C1 + C3 but complete, in P. (Protallinnella) tricostata (Sarv, 1963) it is absent, and in P. (C.) bohemica it is still connected with C1 + C3 but is lacking dorsally except for a plica-like cusp which resembles that of P. (Protallinnella) loennaensis (Sarv, pl. 4, figs. 5-8, 10, 1963).

> Velar dimorphism in P. (C.) bohemica is weakly developed and is very similar to that of the steusloffiine Pseudostrepula (cf. Pl. 11, 128, figs., 1, 2 with Schallreuter, Geologie 15, pl. 4, figs. 1, 2, 1966 or Palaeontographica A 180, Pl. 25(11), figs. 4, 5, 1983). In the type-species of P. (Piretopsis) and P. (Protallinnella) the dolonal antra seem to be broader and therefore more distinct (Öpik, op. cit., pl. 2, fig. 1b; Henningsmoen, op. cit., pl. 2, fig. 7). Reduced velar dimorphism during phylogeny

also occurs in other steusloffiines (eg Steusloffia, Jaanusson, op. cit., 339).

On Ar. 39170 one tecnomorph, much smaller than all the sympatric P. bohemica valves, is distinguished mainly by the total absence of cristae and its highly spinose lobes and velum. It may be conspecific with *P. bohemica*, but this is not certain owing to the lack of intermediate sized larvae.

Distribution:

With certainty only from the type locality. Recorded (material not seen) from elsewhere in Czechoslovakia from Černin and other localities in the Vinice Fm (= Černín Fm) and from the underlying Letná Fm (lower Caradoc) of Blýskava, Chrustenice, Dlouhá hora, Petrovka, Drábov and possibly Běřín and other localities (Přibyl, 205, 1966); also from the underlying Libeň Fm. upper Llandeilo (Havlícěk & Vaněk, op. cit., 53).

ON BAIRDOPPILATA KALAKOTENSIS SINGH & TEWARI

by John W. Neale & Pratap Singh (University of Hull, & 33 Khur Bura, Dehra Dun, India)

Bairdoppilata kalakotensis Singh & Tewari, 1966

1966 Bairdoppilata kalakotensis sp. nov. P. Singh & B. S. Tewari in B. S. Tewari & P. Singh, Cent. Advan. Study in Geology, Panjab University, Chandigarh, 3, 118. pl. 1, figs. 1a-d.

? 1968 Bairdoppilata jaswanti sp. nov. S. N. Singh & Misra, J. Pal. Soc. India, 11, 26, pl. 11, fig. 1, non. pl. 10, figs. 9, 10.

Holotype: University of Lucknow, India, coll. no. L.U. 216.

[Paratype: L.U. 217].

Type locality: Sample 22; dark grey, fossiliferous, argillaceous limestone of the Kalakot Formation, Subathu Group, late early Eocene. About 150ft. above road level in a cliff on the western side of the road

leading to Gua from Beragua and situated at a distance of about 800 feet \$15°W from the opening of the Beragua Mine in the Kalakot Coalfield (Survey of India topographic sheet 43K/8), Nawshera

and Rajouri Tehsils of Poonch District, Jammu and Kashmir State, India (Text fig. 1).

Figured specimens: University of Lucknow, India, nos. L.U. 216 (holotype, car. Pl. 11, 138, figs. 1, 2; Pl. 11, 140, fig. 2)

and L.U. 217 (car.: Pl. 11, 140, figs. 1, 3). Both from the type locality.

Diagnosis: Carapace large, subtriangular. Dorsal margin arched, ventral margin convex. Upper half of anterior end rounded, posterior end somewhat drawn out below middle line. Left valve larger, anterodorsal overlap quite pronounced as compared to posterodorsal and mid-dorsal, ventral overlap pronounced. Teeth distinct on anterodorsal and posterodorsal angles. Highest in middle; lateral outline

in dorsal and ventral views strongly convex, dorsal margin on anterior side curved and ventral margin strongly curved in middle region.

Explanation of Plate 11, 138

Figs. 1, 2, car. (holotype, **L.U. 216**, $1330 \mu m$ long): fig. 1, ext. rt. lat.; fig. 2, ext. lt. lat. Scale A $(200 \mu m; \times 132)$, figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 139

Bairdoppilata kalakotensis (3 of 4)

Remarks:

This species is close to Bairdia subdeltoidea (Munster) of Latham (Trans. R. Soc. Edin., 59, 39-40 1938), from the Palaeocene of Pakistan. Latham's form (length = 1340 µm) is similar in size but differs in being higher anteriorly with a steeper anterodorsal slope and less concave anterodorsal and more convex anteroventral margins in the right valve. The apparent projection of the posterior end of the right valve in Latham's specimen appears due to the absence of the left valve extremity because of breakage (as ascertained by optical microscopy). Bairdia subdeltoidea (Oligocene of W Germany) differs from both in its shorter, straighter anterodorsal margin and less sloping centrodorsal margin and Latham's form will eventually need a new name. Bairdoppilata poddari Lubimova & Mohan (Bull. Geol. Min. Met. Soc. India, 22, 21-22, 1960) is higher in proportion to length and otherwise differs in much the same way as B. subdeltoidea. In 1972 Khosla (Micropaleontology, 18, 484) referred S. N. Singh and Misra's B. jaswanti (Eocene Fuller's Earth, Kolayatji area, Bikaner, Rajasthan) to B. poddari. However, Singh and Misra's second figured specimen (p. 11,

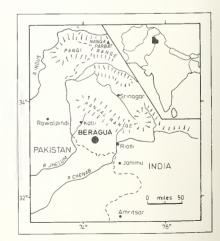

fig. 1) is closer to *B. kalakotensis* and in view of the length they give for *B. jaswanti* (950 µm) could be a juvenile of the present species. We have not examined the originals so place it only questionably in the synonymy of *Bairdoppilata kalakotensis*. The typical subtriangular carapace shape, the very steep posterodorsal and steep anterodorsal slopes of the dorsal margin and all round overlap of the left valve allow *Bairdoppilata kalakotensis* to be distinguished from the associated *Bairdia beraguaensis*, *Bairdia kalakotensis* (see *Stereo-Atlas of Ostracod Shells* 11, 141-144 & 145-148 respectively) and *Bairdia jammmuensis* Singh & Tewari.

Distribution: Late early Eocene Kalakot Formation, Subathu Group, Jammu and Kashmir State. Also the Ghotaru no. 1 well of Rajasthan (in prep.).

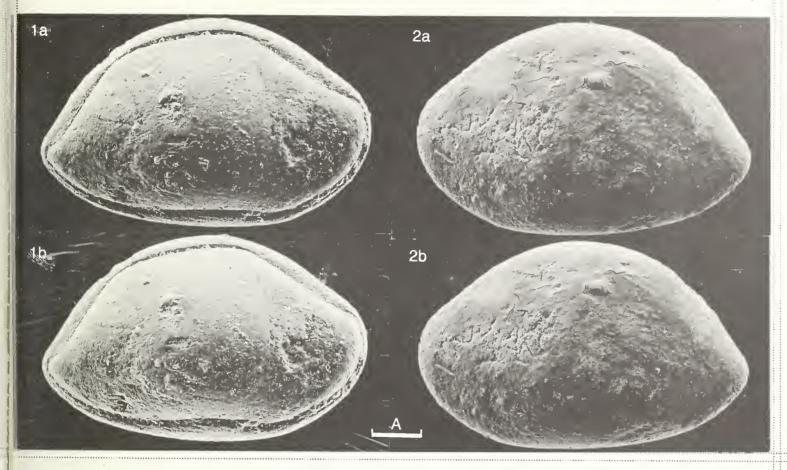

Explanation of Plate 11, 140

ON BAIRDIA BERAGUAENSIS SINGH & TEWARI

by Pratap Singh (33 Khur Bura, Dehra Dun, India)

Bairdia beraguaensis Singh & Tewari, 1966

Bairdia beraguaensis sp. nov. P. Singh & B. S. Tewari in B. S. Tewari & P. Singh, Cent. Advan. Study in Geology, Panjab University, Chandigarh, 3, 119, pl. 1, figs. 4a-d.

Holotype: University of Lucknow, India, no. L.U. 214.

[Paratype: L.U. 215].

Type locality: Sample 22; dark grey, fossiliferous, argillaceous limestone of the Kalakot Formation, Subathu

Group, late early Eocene. About 150ft above road level in a cliff on the western side of the road leading to Gua from Beragua and situated at a distance of about 800 feet S15°W from the opening of the Beragua Mine in the Kalakot Coalfield (Survey of India topographic sheet 43K/8), Nawshera and Rajouri Tehsils of Poonch District, Jammu and Kashmir State, India (see Neale & Singh, Stereo-

Atlas of Ostracod Shells, 11, 139, text-fig. 1).

Figured specimens: University of Lucknow, India, nos. L.U. 214 (holotype, car.: Pl. 11, 142, fig. 1; Pl. 11, 144, fig. 2)

and L.U. 215 (car.: Pl. 11, 142, fig. 2; Pl. 11, 144, figs. 1, 3). Both specimens are from the type

locality.

Explanation of Plate 11, 142

Fig. 1, car., ext. rt. lat. (holotype, **L.U. 214**, $1005 \mu m$ long); fig. 2, car., ext. lt. lat. (paratype, **L.U. 215**, $1002 \mu m$ long). Scale A ($200 \mu m$; $\times 99$), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 143

Bairdia beraguaensis (3 of 4)

Diagnosis: Carapace elongate. Dorsal margin subarched, anterodorsal margin slightly concave, posterodorsal

margin markedly concave, mid-ventral margin slightly convex. Angularly rounded anterior end, posterior and constricted and produced. Larger left valve overlaps right valve along dorsal and mid-posterior to mid-ventral regions. Height is half length, highest at mid-length. Lateral outline in dorsal and ventral views convex with both ends compressed, dorsal and ventral margins slightly

curved.

Remarks: Bairdiacea are particularly well represented in the Eocene of Jammu and Kashmir State, this species

being one of six recorded (see Tewari & Singh, op. cit.). B. beraguaensis differs from Bairdoppilata kalakotensis Singh & Tewari, Bairdia kalakotensis Singh & Tewari (see Stereo-Atlas of Ostracod Shells 11, 137-140 & 145-148 respectively) and Bairdia jammuensis Singh & Tewari in its promi-

nent beak-like projection at the posterior end.

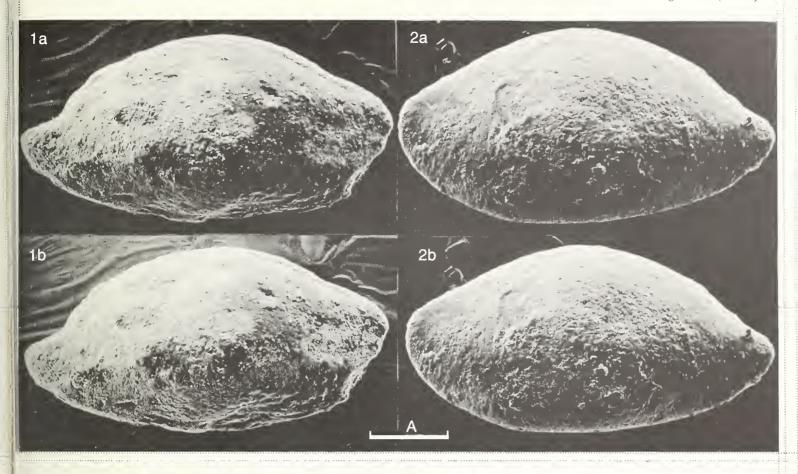

Distribution: Bairdia beraguaensis occurs in the late early Eocene Kalakot Formation of the Subathu Group

exposed in Jammu & Kashmir State, India.

Explanation of Plate 11, 144

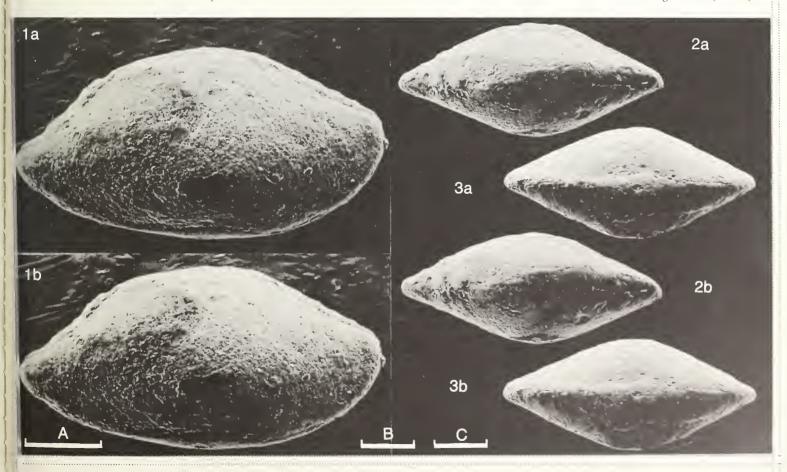

Figs. 1, 3, car. (paratype, L.U. 215, 1002 μ m long): fig. 1, ext. rt. lat.; fig. 3, ext. vent. Fig. 2, car., ext. dors. (holotype, L.U. 214, 1005 μ m long).

Scale A (200 μ m; ×99), fig. 1; Scale B (200 μ m; ×70), fig. 2; Scale C (200 μ m; ×66), fig. 3.

Bairdia beraguaensis (4 of 4)

ON BAIRDIA KALAKOTENSIS SINGH & TEWARI

by Pratap Singh (33 Khur Bura, Dehra Dun, India)

Bairdia kalakotensis Singh & Tewari, 1966

Bairdia kalakotensis sp. nov. P. Singh & B. S. Tewari in B. S. Tewari & P. Singh, Cent. Advan. Study in Geology, Panjab University, Chandigarh, 3, 118, pl. 1., figs. 2a-d.

Holotype: University of Lucknow coll. no. L.U. 210.

[Paratype: L.U. 211].

Type locality: Sample 22; dark grey, fossiliferous, argillaceous limestone of the Kalakot Formation, Sabuthu

Group, late early Eocene. About 150ft above road level in a cliff on the western side of the road leading to Gua from Beragua and situated at a distance of about 800 feet, S15°W from the opening of the Beragua Mine in the Kalakot Coalfield (Survey of India topographic sheet 43K/8), Nawshera and Rajouri Tehsils of Poonch District, Jammu and Kashmir State, India (see Neale & Singh, Stereo-

Atlas of Ostracod Shells 11, 139, text-fig. 1).

Figured specimens: University of Lucknow, India, nos. L.U. 210 (holotype, car.: Pl. 11, 146, figs. 1, 2; Pl. 11, 148, figs. 2,

3) and L.U. 211 (car.: Pl. 11, 148, fig. 1). Both specimens are from the type locality.

Explanation of Plate 11, 146

Figs. 1, 2, car. (holotype, L.U. 210, $800\mu m$ long): fig. 1, ext. rt. lat.; fig. 2, ext. lt. lat. Scale A ($200\mu m$; × 118), figs. 1, 2.

Stereo-Atlas of Ostracod Shells 11, 147

Bairdia kalakotensis (3 of 4)

Diagnosis: Carapace elongate. Dorsal margin sub-arched, posterodorsal slope long and somewhat concave in

posterior region, ventral margin fairly straight and inclined upward anteriorly, making pronounced anteroventral angle. Anterior end broadly rounded, posterior end angularly rounded. Left valve larger than right and overlaps all along dorsal margin and mid-ventral margin. Height is half length; highest part of carapace at mid-length. Carapace ovate in dorsal and ventral views, compressed at

anterior and posterior ends; dorsal and ventral margins curved. Valves punctate.

Remarks: B. kalakotensis differs from B. beraguensis Singh & Tewari (see Stereo-Atlas of Ostracod Shells 11,

141-144, 1984) in not having a beak like projection at the posterior end, and its more arched dorsal margin and convex ventral margin distinguish it from *B. jammuensis* Singh & Tewari. Its elongate carapace in lateral view and its broadly rounded anterior end separate *Bairdia kalakotensis* from *Bairdoppilata kalakotensis* Singh & Tewari (see *Stereo-Atlas of Ostracod Shells*, 11, 137-140, 1984).

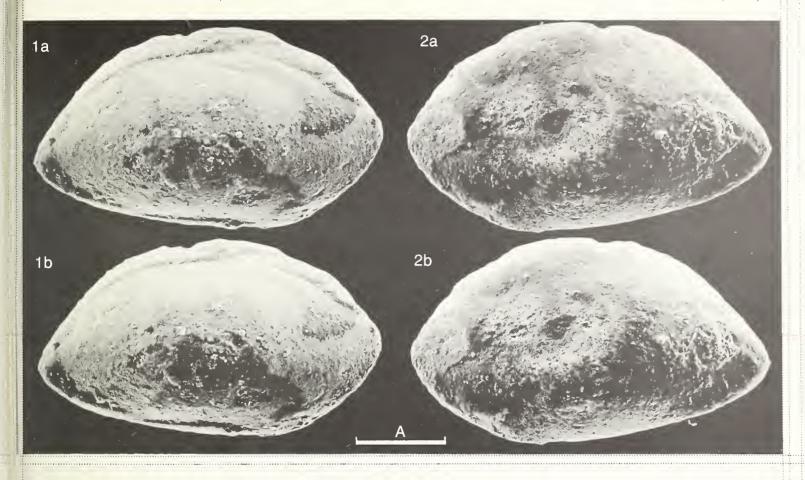

Distribution: Bairdia kalakotensis occurs in the late early Eocene Kalakot Formation of the Subathu Group

exposed in Jammu and Kashmir State, India.

Explanation of Plate 11, 148

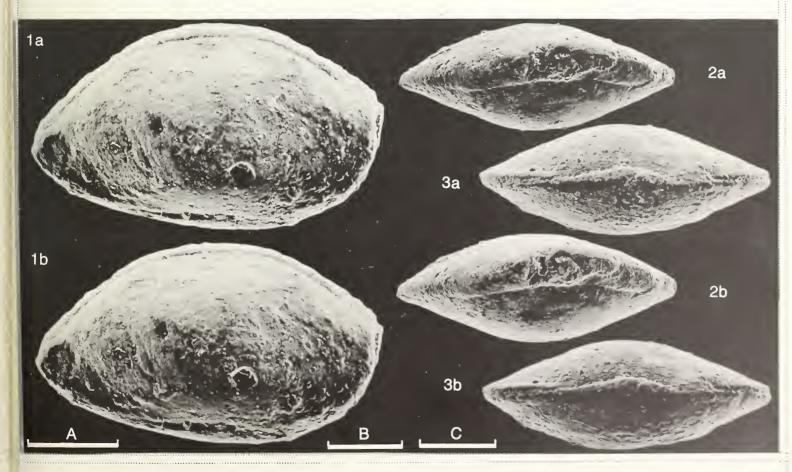

Fig. 1, car., ext. rt. lat. (paratype, **L.U. 211**, 840 μm long); figs. 2, 3, car. (holotype, **L.U. 210**, 800 μm long): fig. 2, ext. dors.; fig. 3, ext. vent.

Scale A (200 μ m; ×116), fig. 1; Scale B (200 μ m; ×91), fig. 2; scale C (200 μ m; ×98), fig. 3.
